

ROUNDING ERROR ANALYSIS OF MIXED PRECISION BLOCK HOUSEHOLDER QR ALGORITHMS

L. MINAH YANG, ALYSON FOX, AND GEOFFREY SANDERS

Abstract. Although mixed precision arithmetic has recently garnered interest for training dense neural networks, many other applications could benefit from the speed-ups and lower storage if applied appropriately. The growing interest in employing mixed precision computations motivates the need for rounding error analysis that properly handles behavior from mixed precision arithmetic. We present a framework for mixed precision analysis that builds on the foundations of rounding error analysis presented in [14] and demonstrate its practicality by applying the analysis to various Householder QR Algorithms.

1. Introduction. The accuracy of a numerical algorithm depends on several factors, including numerical stability and well-conditionedness of the problem, both of which may be sensitive to rounding errors, the difference between exact and finite-precision arithmetic. Low precision floats use fewer bits than high precision floats to represent the real numbers and naturally incur larger rounding errors. Therefore, error attributed to round-off may have a larger influence over the total error when using low precision, and some standard algorithms may yield insufficient accuracy when using low precision storage and arithmetic. However, many applications exist that would benefit from the use of lower precision arithmetic and storage that are less sensitive to floating-point round off error, such as clustering or ranking graph algorithms [?] or training dense neural networks [19], to name a few.

Many computing applications today require solutions quickly and often under low size, weight, and power constraints (low SWaP), e.g., sensor formation, etc. Computing in low-precision arithmetic offers the ability to solve many problems with improvement in all four parameters. Utilizing mixed precision, one can achieve similar quality of computation as high-precision and still achieve speed, size, weight, and power constraint improvements. There have been several recent demonstrations of computing using half-precision arithmetic (16 bits) achieving around half an order to an order of magnitude improvement of these categories in comparison to double precision (64 bits). Trivially, the size and weight of memory required for a specific problem is $4\times$. Additionally, there exist demonstrations that the power consumption improvement is similar [?]. Modern accelerators (e.g., GPUs, Knights Landing, or Xeon Phi) are able to achieve this factor or better speedup improvements. Several examples include: (i) $2\text{--}4\times$ speedup in solving dense large linear equations [12, 13], (ii) $12\times$ speedup in training dense neural networks, and (iii) $1.2\text{--}10\times$ speedup in small batched dense matrix multiplication [1] (up to $26\times$ for batches of tiny matrices). Training deep artificial neural networks by employing lower precision arithmetic to various tasks such as multiplication [7] and storage [8] can easily be implemented on GPUs and are already a common practice in data science applications.

The low precision computing environments that we consider are *mixed precision* settings, which are designed to imitate those of new GPUs that employ multiple precision types for certain tasks. For example, Tesla V100's TensorCores perform matrix products of half precision input data with exact products and single precision (32 bits) summation accumulate [3]. The existing rounding error analyses are built within what we call a *uniform precision* setting, which is the assumption that all arithmetic operations and storage are performed via the same precision. In this work, we

This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344 and was supported by the LLNL-LDRD Program under Project No. 17-SI-004, LLNL-JRNL-795525-DRAFT.

develop a framework for deterministic mixed precision rounding error analysis, and explore half-precision Householder QR factorization (HQR) algorithms for data and graph analysis applications. QR factorization is known to provide a backward stable solution to the linear least squares problem and thus, is ideal for mixed precision.

However, additional analysis is needed as the additional round-off error will effect orthogonality, and thus the accuracy of the solution. Here, we focus on analyzing specific algorithms in a specific set of types (IEEE754 half (fp16), single (fp32), and double(fp64)), but the framework we develop could be used on different algorithms or different floating point types (such as bfloat16 in [22]).

This work discusses several aspects of using mixed precision arithmetic: (i) error analysis that can more accurately describe mixed precision arithmetic than existing analyses, (ii) algorithmic design that is more resistant against lower numerical stability associated with lower precision types, and (iii) an example where mixed precision implementation performs as sufficiently as double-precision implementations. Our key findings are that the new mixed precision error analysis produces tighter error bounds, that some block QR algorithms by Demmel et al. [10] are able to operate in low precision more robustly than non-block techniques, and that some small-scale benchmark graph clustering problems can be successfully solved with mixed precision arithmetic.

2. Background: Build up to rounding error analysis for inner products. In this section, we introduce the basic motivations and tools for mixed precision rounding error analysis needed for the *QR factorization*. A matrix $\mathbf{A} \in \mathbb{R}^{m \times n}$ for $m \geq n$ can be written as

$$\mathbf{A} = \mathbf{QR} = [\mathbf{Q}_1 \quad \mathbf{Q}_2] \begin{bmatrix} \mathbf{R}_1 \\ \mathbf{0}_{m-n \times n} \end{bmatrix} = \mathbf{Q}_1 \mathbf{R}_1,$$

where an orthogonal $\mathbf{Q} \in \mathbb{R}^{m \times m}$ and an upper trapezoidal \mathbf{R} form a *full* QR factorization, and $\mathbf{Q}_1 \in \mathbb{R}^{m \times n}$, $\mathbf{R}_1 \in \mathbb{R}^{n \times n}$ form a *thin* QR factorization. If \mathbf{A} is full rank then the columns of \mathbf{Q}_1 are orthonormal (i.e. $\mathbf{Q}_1^\top \mathbf{Q}_1 = \mathbf{I}_{n \times n}$) and \mathbf{R}_1 is upper triangular. In many applications, computing the *thin* decomposition requires less computation and is sufficient in performance. While important definitions are stated explicitly in the text, Table 1 serves to establish basic notation.

Symbol(s)	Definition(s)	Section(s)
\mathbf{x}, \mathbf{A}	Vector, matrix	2
\mathbf{Q}	Orthogonal factor $\mathbf{A} \in \mathbb{R}^{m \times n}$: m -by- m (full) or m -by- n (thin)	2
\mathbf{R}	Upper triangular or trapezoidal factor of $\mathbf{A} \in \mathbb{R}^{m \times n}$: m -by- n (full) or n -by- n (thin)	2
$\text{fl}(\mathbf{x}), \hat{\mathbf{x}}$	Quantity \mathbf{x} calculated from floating point operations	2.1
b, t, μ, η	Base/precision/mantissa/exponent bits	2.1
k	Number of successive FLOPs	2.1
$u^{(q)}$	Unit round-off for precision t_q and base b_q : $\frac{1}{2}b_q^{1-t_q}$	2.1
$\delta^{(q)}$	Quantity bounded by: $ \delta^{(q)} < u^{(q)}$	2.1
$\gamma_k^{(q)}, \theta_k^{(q)}$	$\frac{ku^{(q)}}{1-ku^{(q)}}$, Quantity bounded by: $ \theta_k^{(q)} \leq \gamma_k^{(q)}$	2.1

TABLE 1
Basic definitions

Subsection 2.1 introduces basic concepts for rounding error analysis, and Subsection 2.2 exemplifies the need for mixed precision rounding error analysis for the inner product.

2.1. Basic rounding error analysis of floating point operations. We use and analyze the IEEE 754 Standard floating point number systems, shown in Table 2. Let $\mathbb{F} \subset \mathbb{R}$ denote the space of some floating point number system with base $b \in \mathbb{N}$, precision $t \in \mathbb{N}$, significand $\mu \in \mathbb{N}$, and exponent range $[\eta_{\min}, \eta_{\max}] \subset \mathbb{Z}$. Then every element y in \mathbb{F} can be written as

$$(2.1) \quad y = \pm \mu \times b^{\eta-t},$$

where μ is any integer in $[0, b^t - 1]$ and η is an integer in $[\eta_{\min}, \eta_{\max}]$. Although operations we use on \mathbb{R} cannot be replicated exactly due to the finite cardinality of \mathbb{F} , we can still approximate the accuracy of analogous floating point operations (FLOPs). We adopt the rounding error analysis tools described in [14], which allow a relatively simple framework for formulating error bounds for complex linear algebra operations. An analysis of FLOPs (see Theorem 2.2 [14]) shows that the relative error is controlled by the unit round-off, $u := \frac{1}{2}b^{1-t}$ in uniform precision settings. In mixed precision settings we denote the higher precision unit round-off with $u^{(h)}$ (h for high) and the lower precision unit round-off with $u^{(l)}$ (l for low).

Name	b	t	# of exponent bits	η_{\min}	η_{\max}	unit round-off u
fp16 (IEEE754 half)	2	11	5	-15	16	4.883e-04
fp32 (IEEE754 single)	2	24	8	-127	128	5.960e-08

TABLE 2
IEEE754 formats and their primary attributes.

Let ‘op’ be any basic operation from the set $\text{OP} = \{+, -, \times, \div\}$ and let $x, y \in \mathbb{R}$. The true value $(x \text{ op } y)$ lies in \mathbb{R} , and it is rounded using some conversion to a floating point number, $\text{fl}(x \text{ op } y)$, admitting a rounding error. The IEEE 754 Standard requires *correct rounding*, which rounds the exact solution $(x \text{ op } y)$ to the closest floating point number and, in case of a tie, to the floating point number that has a mantissa ending in an even number. *Correct rounding* gives us an assumption for the error model where a single basic floating point operation yields a relative error, δ , bounded in the following sense:

$$(2.2) \quad \text{fl}(x \text{ op } y) = (1 + \delta)(x \text{ op } y), \quad |\delta| \leq u, \quad \text{op} \in \{+, -, \times, \div\}.$$

We use (2.2) as a building block in accumulating errors from successive FLOPs. Successive operations introduce multiple rounding error terms, and keeping track of all errors is challenging. Lemma 2.1 introduces a convenient and elegant bound that simplifies accumulation of rounding error.

LEMMA 2.1 (Lemma 3.1 [14]). *Let $|\delta_i| < u$, $\rho_i = \pm 1$ for $i = 1 : k$, and $ku < 1$. Then,*

$$(2.3) \quad \prod_{i=1}^k (1 + \delta_i)^{\rho_i} = 1 + \theta_k, \quad \text{where } |\theta_k| \leq \frac{ku}{1 - ku} =: \gamma_k.$$

Additionally, we define $\tilde{\theta}_k$ that satisfies $|\tilde{\theta}_k| \leq \tilde{\gamma}_k$, where $\tilde{\gamma}_k = \frac{cku}{1 - cku}$ for a small integer, $c > 0$.

In other words, θ_k represents the accumulation of rounding errors from k successive operations, and it is bounded by γ_k . In more complicated routines shown in later sections, we use the tilde notation ($\tilde{\gamma}_k$) to permit only keeping track of the leading order error terms. Applying this lemma to the computation of $x + y + z$, where $x, y, z \in \mathbb{R}$, results in

$$(2.4) \quad \text{fl}(x + y + z) = (1 + \delta')((1 + \delta)(x + y) + z) = (1 + \theta_2)(x + y) + (1 + \theta_1)z,$$

100 where $|\delta|, |\delta'| < u$. Since $|\theta_1| \leq \gamma_1 < \gamma_2$, we can further simplify (2.4) to

$$101 \quad (2.5) \quad \text{fl}(x + y + z) = (1 + \theta'_2)(x + y + z), \quad \text{where} \quad |\theta'_2| \leq \gamma_2,$$

102 at the cost of a slightly larger upper bound. Note that both $|\theta_2|, |\theta'_2|$ are bounded above by γ_2 .
 103 Typically, error bounds formed in the fashion of (2.5) are converted to relative errors in order to
 104 put the error magnitudes in perspective. The relative error bound for our example is

$$105 \quad |(x + y + z) - \text{fl}(x + y + z)| \leq \gamma_2 |x + y + z|$$

106 when we assume $x + y + z \neq 0$.

107 Although Lemma 2.1 requires $ku < 1$, we actually need $ku < \frac{1}{2}$ to maintain a meaningful
 108 relative error bound as this assumption implies $\gamma_k < 1$ and guarantees a relative error below
 109 100%. Since higher precision types have smaller unit round-offs, they can tolerate more successive
 110 FLOPs than lower precision floating types before reaching $\gamma_m = 1$. For example, the IEEE types
 111 introduced in Table 2 meet this requirement at $1/2 = 2^{10} u^{(\text{fp16})} = 2^{23} u^{(\text{fp32})} = 2^{52} u^{(\text{fp64})}$. Thus,
 112 accumulated rounding errors in lower precision types can lead to an instability with fewer operations
 113 in comparison to higher precision types and prompts us to evaluate whether existing algorithms
 114 can be naively adapted for mixed precision arithmetic.

115 **2.2. Rounding Error Example for the Inner Product.** We now consider computing the
 116 inner product of two vectors to clearly illustrate how this situation restricts rounding error analysis
 117 in fp16. An error bound for an inner product of m -length vectors is

$$118 \quad (2.6) \quad |\mathbf{x}^\top \mathbf{y} - \text{fl}(\mathbf{x}^\top \mathbf{y})| \leq \gamma_m |\mathbf{x}^\top \mathbf{y}|, \quad \mathbf{x}, \mathbf{y} \in \mathbb{R}^m$$

119 as shown in [14]. While this result does not guarantee a high relative accuracy when $|\mathbf{x}^\top \mathbf{y}| \ll$
 120 $|\mathbf{x}^\top \mathbf{y}|$, high relative accuracy is expected in some special cases. For example, let $\mathbf{x} = \mathbf{y}$. Then we
 121 have exactly $|\mathbf{x}^\top \mathbf{x}| = |\mathbf{x}^\top \mathbf{x}| = \|\mathbf{x}\|_2^2$, which leads to a forward error: $|\|\mathbf{x}\|_2^2 - \text{fl}(\|\mathbf{x}\|_2^2)| \leq \gamma_m \|\mathbf{x}\|_2^2$.
 122 Since vectors of length m accumulate rounding errors that are bounded by γ_m , the dot products
 123 of vectors computed in fp16 already face a 100% relative error bound in the worst-case scenario
 124 ($\gamma_{512}^{(\text{fp16})} = 1$).

125 A simple numerical experiment shows that the standard deterministic error bound is too pes-
 126 simistic and cannot be practically used to approximate rounding error for half-precision arithmetic.
 127 In this experiment, we generated 2 million random fp16 vectors of length 1024 from two random
 128 distributions: the standard normal distribution, $N(0, 1)$, and the uniform distribution over $(0, 1)$.
 129 Half precision arithmetic was simulated by calling alg. 1, which was proven to be a faithful simula-
 130 tion in [16], for every FLOP (multiplication and addition for the dot product). The relative error
 131 in this experiment is formulated as the LHS in Equation 2.6 divided by $|\mathbf{x}^\top \mathbf{y}|$ and all operations
 132 outside of calculating $\text{fl}(\mathbf{x}^\top \mathbf{y})$ are executed by casting up to fp64 and using fp64 arithmetic. Table 3
 133 shows some statistics from computing the relative error for simulated fp16 dot products of random
 134 1024-length vectors.

135 We see that the inner products of vectors sampled from the standard normal distribution have
 136 backward relative errors that do not deviate much from the unit round-off ($\mathcal{O}(1\text{e-}4)$), whereas
 137 the vectors sampled from the uniform distribution tend to accumulate larger errors on average
 138 ($\mathcal{O}(1\text{e-}3)$). Even so, the theoretical upper error bound of 100% is far too pessimistic as the
 139 maximum relative error does not even meet 2% in this experiment. Recent work in developing
 140 probabilistic bounds on rounding errors of floating point operations (see [15, 18]) have shown that

Random Distribution	Average	Stan. Dev.	Maximum
Standard normal	1.621e-04	1.635e-04	3.204e-03
Uniform (0, 1)	6.904e-03	3.265e-03	2.447e-02

TABLE 3

Most importantly, we need error analysis that allows flexibility in precision in order to better our understanding of the impact of rounding errors on computations done on emerging hardware (i.e. GPUs) that support mixed precision. We start by introducing some additional rules from [14] that build on Lemma 2.1 in Lemma 2.2. These rules summarize how to accumulate errors represented by θ 's and γ 's in a *uniform precision* setting.

LEMMA 2.2. For any positive integer k , let θ_k denote a quantity bounded according to $|\theta_k| \leq \frac{k u}{1 - k u} =: \gamma_k$. The following relations hold for positive integers j, n and nonnegative integer k . Arithmetic operations between bounded terms, θ_k 's, are:

$$(2.7) \quad (1 + \theta_k)(1 + \theta_j) = (1 + \theta_{k+j}) \quad \text{and} \quad \frac{1 + \theta_k}{1 + \theta_j} = \begin{cases} 1 + \theta_{k+j}, & j \leq k \\ 1 + \theta_{k+2j}, & j > k \end{cases}.$$

If $\max_{(j,k)} u \leq \frac{1}{2}$ and $n \leq \frac{1}{u k}$, the operations on the bounds, γ 's, are:

$$\begin{aligned} \gamma_k \gamma_j &\leq \gamma_{\min(k,j)}, & n \gamma_k &\leq \gamma_{nk}, \\ \gamma_k + u &\leq \gamma_{k+1}, & \gamma_k + \gamma_j + \gamma_k \gamma_j &\leq \gamma_{k+j}. \end{aligned}$$

Note that all the rules hold when replaced by $\tilde{\gamma}$'s, but result in looser bounds.

We define two mixed precision settings that we use in section 4. In subsection 4.1, we present the block Fused Multiply-Add (bFMA) of NVIDIA's TensorCore (TC) technology, which computes matrix-matrix multiply and accumulate for 4-by-4 blocks, and incorporate it into algs. 5 and 6. Here, we introduce an ad hoc mixed precision setting which we use in subsection 4.2. This is explicitly defined in Assumption 2.3 and is a level-2 BLAS variant of the TC bFMA. Both mixed precision settings define how inner products are computed although the bFMA is only applicable to inner products within matrix products and uses fp16 and fp32 whereas our ad hoc mixed precision setting is applicable to all inner products with any two precision types.

Although our analysis concerns accuracy and stability and leaves out timing results of various hardware, we add a general timing statement to [Assumption 2.3](#) that is analogous to that of TC: the mixed precision FMA inner product performs at least 2 times faster than the inner product in the higher precision. Note that TCs perform matrix-matrix multiply and accumulate up to 8 times faster than fp32, and up to 16 times faster than fp64 (see), and our ad hoc timing assumption is in conservative in comparison. Nonetheless, this gives a vague insight into the trade-offs between speediness and accuracy from some mixed precision computations.

The full precision multiplication in [Assumption 2.3](#) is exact when the low precision type is fp16 and the high precision type of fp32 due to their precisions and exponent ranges. As a quick proof, consider $x^{(\text{fp16})} = \pm\mu_x 2^{\eta_x-11}$, $y^{(\text{fp16})} = \pm\mu_y 2^{\eta_y-11}$ where $\mu_x, \mu_y \in [0, 2^{11}-1]$ and $\eta_x, \eta_y \in [-15, 16]$, and note that the significand and exponent ranges for fp32 are $[0, 2^{24}-1]$ and $[-127, 128]$. Then the product in full precision is

$$x^{(\text{fp16})}y^{(\text{fp16})} = \pm\mu_x\mu_y 2^{\eta_x+\eta_y+2-24},$$

where $\mu_x\mu_y \in [0, (2^{11}-1)^2] \subseteq [0, 2^{24}-1]$ and $\eta_x + \eta_y + 2 \in [-28, 34] \subseteq [-127, 128]$, and therefore is exact. Thus, the summation and the final cast down operations are the only sources of rounding error in this inner product scheme.

ASSUMPTION 2.3. *Let l and h each denote low and high precision types with unit round-off values $u^{(l)}$ and $u^{(h)}$, where $1 \gg u^{(l)} \gg u^{(h)} > 0$. Consider an FMA operation for inner products that take vectors stored in precision l , compute products in full precision, and sum the products in precision h . Finally, the result is then cast back down to precision l . Furthermore, we expect this procedure to be approximately twice as fast as if it were done entirely in the higher precision, and about the same as if it were done entirely in the lower precision.*

We now analyze the rounding error for the inner product scheme described in [Assumption 2.3](#) and hypothesize that the guaranteed accuracy for this mixed precision inner product should be better than that of the low precision inner product and worse than that of the high precision inner product. Let $\mathbf{x}^{(l)}, \mathbf{y}^{(l)}$ be m -length vectors stored in a low precision type (\mathbb{F}_l^m), s_k be the exact k^{th} partial sum, and \hat{s}_k be s_k computed with FLOPs. Then the first three partial sums are,

$$\hat{s}_1 = \text{fl}(\mathbf{x}[1]\mathbf{y}[1]) = \mathbf{x}[1]\mathbf{y}[1], \quad \hat{s}_2 = \text{fl}(\hat{s}_1 + \mathbf{x}[2]\mathbf{y}[2]) = (\mathbf{x}[1]\mathbf{y}[1] + \mathbf{x}[2]\mathbf{y}[2]) (1 + \delta_1^{(h)}),$$

$$\hat{s}_3 = \text{fl}(\hat{s}_2 + \mathbf{x}[3]\mathbf{y}[3]) = \left[(\mathbf{x}[1]\mathbf{y}[1] + \mathbf{x}[2]\mathbf{y}[2]) (1 + \delta_1^{(h)}) + \mathbf{x}[3]\mathbf{y}[3] \right] (1 + \delta_2^{(h)}).$$

We see a pattern emerging. The error for an m -length vector dot product is then

$$(2.8) \quad \hat{s}_m = (\mathbf{x}[1]\mathbf{y}[1] + \mathbf{x}[2]\mathbf{y}[2]) \prod_{k=1}^{m-1} (1 + \delta_k^{(h)}) + \sum_{i=3}^n \mathbf{x}[i]\mathbf{y}[i] \left(\prod_{k=i-1}^{m-1} (1 + \delta_k^{(h)}) \right).$$

Using [Lemma 2.1](#), we further simplify and form componentwise backward errors with

$$(2.9) \quad \text{fl}(\mathbf{x}^\top \mathbf{y}) = (\mathbf{x} + \Delta \mathbf{x})^\top \mathbf{y} = \mathbf{x}^\top (\mathbf{y} + \Delta \mathbf{y}) \quad \text{for } |\Delta \mathbf{x}| \leq \gamma_{m-1}^{(h)} |\mathbf{x}|, \quad |\Delta \mathbf{y}| \leq \gamma_{m-1}^{(h)} |\mathbf{y}|.$$

Casting down to \mathbb{F}_l without underflow or overflow results in backward errors,

$$(2.10) \quad \text{castdown}(\text{fl}(\mathbf{x}^\top \mathbf{y})) = (\mathbf{x} + \Delta \mathbf{x} + \tilde{\Delta} \mathbf{x})^\top \mathbf{y} = \mathbf{x}^\top (\mathbf{y} + \Delta \mathbf{y} + \tilde{\Delta} \mathbf{y}),$$

where $|\Delta \mathbf{x} + \tilde{\Delta} \mathbf{x}| \leq ((1 + u^{(l)})(1 + \gamma_{m-1}^{(h)}) - 1) |\mathbf{x}|$ and $|\Delta \mathbf{y} + \tilde{\Delta} \mathbf{y}| \leq ((1 + u^{(l)})(1 + \gamma_{m-1}^{(h)}) - 1) |\mathbf{y}|$. Our hypothesis is indeed true since,

$$\gamma_m^{(h)} < u^{(l)} + \gamma_{m-1}^{(h)} + u^{(l)} \gamma_{m-1}^{(h)} < \gamma_m^{(l)},$$

where the lower and upper bounds are derived from the uniform precision error bound in (2.6). Equation (2.10) shows us that the two larger error terms are from the higher precision summation, $\gamma_{m-1}^{(h)}$, and the cast down operation, $u^{(l)}$. We can measure the impact of the cast down step relative to the length of the vector, m , and the disparity in the two precisions, $M_{l,h} := u^{(l)}/u^{(h)}$, since these two factors determine which one out of $u^{(l)}$ and $mu^{(h)}$ is the leading order term. There are 3 cases to consider.

Case 1: ($m \ll M_{l,h}$) The leading order term is $u^{(l)}$. The mixed precision inner product has a smaller worst case error bound than the bound of the low precision inner product ($mu^{(l)}$) with no apparent improvements in speed. On the other hand, $u^{(l)}$ is a larger upper bound than that of the high precision inner product ($mu^{(h)} = \frac{m}{M_{l,h}}u^{(l)}$), although it was computed approximately twice as fast. It is likely that this factor of $M_{l,h}/m$ increase in the worst case error bound is unwanted even when considering the speed-up.

Case 2: ($m = M_{l,h}$) Both terms are now leading order. This is still an improvement in comparison to the lower precision arithmetic as the error bound is reduced from $mu^{(l)}$ to $2u^{(l)}$. Comparing this to the high precision inner product shows that the error bound has doubled from $mu^{(h)}$ to $2mu^{(h)}$, but gained a factor of 2 in speed instead. One can argue that the loss in accuracy guarantee and the improvement in speed cancel each other out especially if $2mu^{(h)} \ll 1$ or if the speed-up greatly exceeds a factor of 2.

Case 3: ($m \gg M_{l,h}$) Now $\gamma_{m-1}^{(h)}$ is the leading order term. As in the above two cases, this is an improvement in the context of the low precision accuracy since the error has been reduced from $\gamma_m^{(l)}$ to $\gamma_{m/M_{l,h}}^{(l)} \equiv \gamma_m^{(h)}$. Since $u^{(l)} = M_{l,h}u^{(h)} \ll mu^{(h)}$, the mixed precision error bound has the same order as the error bound from carrying the computation out in the higher precision. Therefore, we can expect about the same level of accuracy but a factor of 2 or greater reduction in speed when compared to the higher precision.

While the above cases establish 3 regimes of trade-offs between accuracy and speed in mixed precision computing, the remainder of this paper focuses only on accuracy and does not consider the impact of mixed precision computations on speed. Readers should refer to timing studies such as Finally, we present alternative representations of the error bound in (2.10),

$$(1 + u^{(l)})(1 + \gamma_{m-1}^{(h)}) - 1 \leq \gamma_{M_{l,h}+m-1}^{(h)} = \gamma_{1+(m-1)/M_{l,h}}^{(l)}, \quad M_{l,h} = u^{(l)}/u^{(h)},$$

$$(1 + u^{(l)})(1 + \gamma_{m-1}^{(h)}) - 1 \leq u^{(l)} + \gamma_{m-1}^{(h)} + \min\{u^{(l)}, \gamma_{m-1}^{(h)}\}, \quad \gamma_{m-1}^{(h)} < 1,$$

where the rules from Lemma 2.2 were directly applied. Both alternative bounds are only slightly larger than the original bound shown on the LHS and remain in the same order. The first is useful when comparing against the low or the high precision, whereas the second keeps track of the error bounds in both precisions. We summarize these ways of combining γ terms of different precisions in Lemma 2.4,

LEMMA 2.4. For any nonnegative integers k_l, k_h and some precision q defined with respect to the unit round-off, $u^{(q)}$, define $\gamma_k^{(q)} := \frac{ku^{(q)}}{1-ku^{(q)}}$. Consider a low precision and a high precision where $1 \gg u^{(l)} \gg u^{(h)} > 0$, and k_l, k_h that satisfy $\max\{\gamma_{k_h}^{(h)}, \gamma_{k_l}^{(l)}\} < 1/2$. Then the following rules help us accumulate γ 's of different precisions,

$$(2.11) \quad \gamma_{k_h}^{(h)} \gamma_{k_l}^{(l)} \leq \min\{\gamma_{k_h}^{(h)}, \gamma_{k_l}^{(l)}\},$$

$$(2.12) \quad (1 + \tilde{\gamma}_{k_l}^{(l)})(1 + \tilde{\gamma}_{k_h}^{(h)}) - 1 = \tilde{\gamma}_{k_l}^{(l)} + \tilde{\gamma}_{k_h}^{(h)}.$$

Note that (2.12) drops the term $\tilde{\gamma}_{k_l}^{(l)}\tilde{\gamma}_{k_h}^{(h)}$ since both $\tilde{\gamma}_{k_l}^{(l)}$ and $\tilde{\gamma}_{k_h}^{(h)}$ are larger than their product and this product can be swept under the small integer $c > 0$ assumption implicitly included in the tilde notation. Equations (2.9) and (2.10) are crucial for our analysis in section 4 since the two mixed precision settings add `castdown` operations at different parts of the HQR algorithms we consider. In general, error bounds in the fashion of (2.9) can be used before the cast down operations and the action of the cast down is best represented by error bounds similar to (2.10).

We have demonstrated a need for rounding error analysis that is accurate for mixed precision procedures and analyzed the inner product in an ad hoc mixed precision inner product that mimics the TensorCore bFMA. We will use this to analyze various Householder (HH) QR factorization algorithms. Algorithms and the general framework for the standard rounding error analysis for these algorithms are introduced in section 3, and both are modified to meet different mixed precision assumptions in section 4.

3. Algorithms and existing round-off error analyses. We introduce the Householder QR factorization algorithm (HQR) in subsection 3.1 and two block variants that use HQR within the block in subsections 3.2 and 3.3. The blocked HQR (BQR) in subsection 3.2 partitions the columns of the target matrix and is a well-known algorithm that uses the WY representation of [5] that utilizes mainly level-3 BLAS operations. In contrast, the Tall-and-Skinny QR (TSQR) in subsection 3.3 partitions rows of the matrix and takes a communication-avoiding divide-and-conquer approach that can be easily parallelized (see [9]). We also present the standard rounding error analysis of these algorithms which will be tweaked for various mixed precision assumptions in section 4.

3.1. Householder QR (HQR). The HQR algorithm uses HH transformations to zero out elements below the diagonal of a matrix (see [17]). We present this as zeroing out all but the first element of some vector, $\mathbf{x} \in \mathbb{R}^m$.

LEMMA 3.1. *Given vector $\mathbf{x} \in \mathbb{R}^m$, there exist a HH vector, \mathbf{v} , and a HH constant, β , that define the HH transformation matrix, $\mathbf{P}_{\mathbf{v}} := \mathbf{I}_m - \beta \mathbf{v} \mathbf{v}^\top$, such that $\mathbf{P}_{\mathbf{v}}$ zeros out \mathbf{x} below the first element. The HH vector and constant are defined via*

$$(3.1) \quad \sigma = -\text{sign}(\mathbf{x}[1])\|\mathbf{x}\|_2, \quad \mathbf{v} = \mathbf{x} - \sigma \hat{\mathbf{e}}_1, \quad \text{and} \quad \beta = \frac{2}{\mathbf{v}^\top \mathbf{v}} = -\frac{1}{\sigma \mathbf{v}[1]}.$$

Note that $\mathbf{P}_{\mathbf{v}}$ is symmetric and orthogonal, $\mathbf{P}_{\mathbf{v}} = \mathbf{P}_{\mathbf{v}}^\top = \mathbf{P}_{\mathbf{v}}^{-1}$. As a result, the transformed vector, $\mathbf{P}_{\mathbf{v}}\mathbf{x} = \sigma \hat{\mathbf{e}}_1$, has the same 2-norm as \mathbf{x} .

3.1.1. HQR: Algorithm. Given $\mathbf{A} \in \mathbb{R}^{m \times n}$ and Lemma 3.1, HQR is done by repeating the following processes until only an upper triangle matrix remains. For $i = 1, 2, \dots, n$,
Step 1) Compute \mathbf{v} and β that zeros out the i^{th} column of \mathbf{A} beneath a_{ii} (see alg. 2), and
Step 2) Apply $\mathbf{P}_{\mathbf{v}}$ to the bottom right partition, $\mathbf{A}[i : m, i : n]$ (lines 4-6 of alg. 3).

Consider the following 4-by-3 matrix example adapted from [14]. Let \mathbf{P}_i represent the i^{th} HH transformation of this algorithm.

$$\mathbf{A} = \begin{bmatrix} \times & \times & \times \\ \times & \times & \times \\ \times & \times & \times \\ \times & \times & \times \end{bmatrix} \xrightarrow{\mathbf{P}_1 \mathbf{A}} \begin{bmatrix} \times & \times & \times \\ 0 & \times & \times \\ 0 & \times & \times \\ 0 & \times & \times \end{bmatrix} \xrightarrow{\mathbf{P}_2 \mathbf{P}_1 \mathbf{A}} \begin{bmatrix} \times & \times & \times \\ 0 & \times & \times \\ 0 & 0 & \times \\ 0 & 0 & \times \end{bmatrix} \xrightarrow{\mathbf{P}_3 \mathbf{P}_2 \mathbf{P}_1 \mathbf{A}} \begin{bmatrix} \times & \times & \times \\ 0 & \times & \times \\ 0 & 0 & \times \\ 0 & 0 & 0 \end{bmatrix}$$

The resulting matrix is the \mathbf{R} factor, $\mathbf{R} := \mathbf{P}_3 \mathbf{P}_2 \mathbf{P}_1 \mathbf{A}$, and the \mathbf{Q} factor for a full QR factorization is $\mathbf{Q} := \mathbf{P}_1 \mathbf{P}_2 \mathbf{P}_3$ since \mathbf{P}_i 's are symmetric. The thin factors for a general matrix $\mathbf{A} \in \mathbb{R}^{m \times n}$ are

$$(3.2) \quad \mathbf{Q}_{\text{thin}} = \mathbf{P}_1 \cdots \mathbf{P}_n \mathbf{I}_{m \times n} \quad \text{and} \quad \mathbf{R}_{\text{thin}} = \mathbf{I}_{m \times n}^\top \mathbf{P}_n \cdots \mathbf{P}_1 \mathbf{A}.$$

Algorithm 2: $\beta, \mathbf{v}, \sigma = \text{hhvec}(\mathbf{x})$. Given a vector $\mathbf{x} \in \mathbb{R}^m$, return $\mathbf{v} \in \mathbb{R}^m$ and $\beta, \sigma \in \mathbb{R}$ that satisfy $(I - \beta \mathbf{v} \mathbf{v}^\top) \mathbf{x} = \sigma \hat{\mathbf{e}}_1$ and $\mathbf{v}[1] = 1$ (see [2, 14]).

Input: \mathbf{x}

Output: \mathbf{v}, σ , and β

```

1  $\mathbf{v} \leftarrow \text{copy}(\mathbf{x})$ 
2  $\sigma \leftarrow -\text{sign}(\mathbf{x}[1]) \|\mathbf{x}\|_2$ 
3  $\mathbf{v}[1] \leftarrow \mathbf{x}[1] - \sigma$ 
4  $\beta \leftarrow -\frac{\mathbf{v}[1]}{\sigma}$ 
5  $\mathbf{v} \leftarrow \mathbf{v} / \mathbf{v}[1]$ 
6 return  $\beta, \mathbf{v}, \sigma$ 

```

Algorithm 3: $\mathbf{V}, \beta, \mathbf{R} = \text{HQR2}(\mathbf{A})$. A Level-2 BLAS implementation of HQR. Given a matrix $\mathbf{A} \in \mathbb{R}^{m \times n}$ where $m \geq n$, return matrix $\mathbf{V} \in \mathbb{R}^{m \times n}$, vector $\beta \in \mathbb{R}^n$, and upper triangular matrix \mathbf{R} . The orthogonal factor \mathbf{Q} can be generated from \mathbf{V} and β .

Input: \mathbf{A}

Output: $\mathbf{V}, \beta, \mathbf{R}$

```

1 Initialize  $\mathbf{V} \leftarrow \mathbf{0}_{m \times n}, \beta \leftarrow \mathbf{0}_m$ 
2 for  $i = 1 : n$  do
3    $\mathbf{v}, \beta, \sigma \leftarrow \text{hhvec}(\mathbf{A}[i : \text{end}, i])$  /* Algorithm 2 */
4    $\mathbf{V}[i : \text{end}, i], \beta_i, \mathbf{A}[i, i] \leftarrow \mathbf{v}, \beta, \sigma$ 
5    $\mathbf{A}[i + 1 : \text{end}, i] \leftarrow \text{zeros}(m - i)$ 
6    $\mathbf{A}[i : \text{end}, i + 1 : \text{end}] \leftarrow \mathbf{A}[i : \text{end}, i + 1 : \text{end}] - \beta \mathbf{v} \mathbf{v}^\top \mathbf{A}[i : \text{end}, i + 1 : \text{end}]$ 
7 return  $\mathbf{V}, \beta, \mathbf{A}[1 : n, 1 : n]$ 

```

3.1.2. HQR: Rounding Error Analysis. Now we present an error analysis for [alg. 3](#) by keeping track of the different operations of [alg. 2](#) and [alg. 3](#).

Calculating the i^{th} HH vector and constant. In [alg. 3](#), we compute the HH vector and constant by using [alg. 2](#) to $\mathbf{A}[i : m, i]$. For now, consider zeroing out any vector $\mathbf{x} \in \mathbb{R}^m$ below its first component with a HH transformation. We first calculate σ as is implemented in line 2 of [alg. 2](#).

$$(3.3) \quad \text{fl}(\sigma) = \hat{\sigma} = \text{fl}(-\text{sign}(\mathbf{x}[1]) \|\mathbf{x}\|_2) = \sigma + \Delta\sigma, \quad |\Delta\sigma| \leq \gamma_{m+1} |\sigma|.$$

Note that the backward error incurred here accounts for an inner product of a vector in \mathbb{R}^m with itself and a square root operation to get the 2-norm. Let $\mathbf{v}'[1] \equiv \mathbf{x}[i] - \sigma$, the penultimate value $\mathbf{v}[1]$ held. The subtraction adds a single additional rounding error via

$$(3.4) \quad \text{fl}(\mathbf{v}'[1]) = \mathbf{v}'[1] + \Delta\mathbf{v}'[1] = (1 + \delta)(\mathbf{x}[i] - \sigma - \Delta\sigma) = (1 + \theta_{m+2})\mathbf{v}'[1]$$

where the last equality is granted because the sign of σ is chosen to prevent cancellation. Since [alg. 2](#) normalizes the HH vector so that its first component is 1, the remaining components of \mathbf{v} are divided by $\text{fl}(\tilde{\mathbf{v}}_1)$ incurring another single rounding error. As a result, the components of \mathbf{v} computed with FLOPs have error $\text{fl}(\mathbf{v}[j]) = \mathbf{v}[j] + \Delta\mathbf{v}[j]$ where

$$(3.5) \quad |\Delta\mathbf{v}[j]| \leq \gamma_{1+2(m+2)} |\mathbf{v}[j]| = \tilde{\gamma}_m |\mathbf{v}[j]| \quad j = 2 : m - i + 1,$$

and $|\Delta\mathbf{v}[1]| = 0$. Since $1 + 2(m + 2) = \mathcal{O}(m)$, we have swept that minor difference between under our use of the $\tilde{\gamma}$ notation defined in [Lemma 2.1](#). Next, we consider the HH constant, β , as is

305 computed in line 4 of [alg. 2](#).

$$306 \quad (3.6) \quad \hat{\beta} = \text{fl}(-\mathbf{v}'[1]/\hat{\sigma}) = -(1+\delta) \frac{\mathbf{v}'[1] + \Delta\mathbf{v}'[1]}{\sigma + \Delta\sigma} = \frac{(1+\delta)(1+\theta_{m+2})}{(1+\theta_{m+1})} \beta$$

$$307 \quad (3.7) \quad = (1+\theta_{3m+5})\beta = \beta + \Delta\beta, \text{ where } |\Delta\beta| \leq \tilde{\gamma}_m\beta.$$

309 We have shown [\(3.6\)](#) to keep our analysis simple in [section 4](#) and [\(3.7\)](#) show that the error incurred
310 from calculating of $\|\mathbf{x}\|_2$ accounts for the vast majority of the rounding error so far. At iteration
311 i , we replace \mathbf{x} with $\mathbf{A}[i : m, i] \in \mathbb{R}^{m-i+1}$ and the i^{th} HH constant and vector $(\hat{\beta}_i, \mathbf{v}_i)$ both have
312 errors bounded by $\tilde{\gamma}_{m-i+1}$.

313 *Applying a Single HH Transformation.* Now we consider lines 4-6 of [alg. 3](#). At iteration i ,
314 we set $\mathbf{A}[i+1 : m, :]$ to zero and replace $\mathbf{A}[i, i]$ with σ computed from [alg. 2](#). Therefore, we
315 now need to calculate the errors for applying a HH transformation to the remaining columns,
316 $\mathbf{A}[i : m, i+1 : n]$ with the computed HH vector and constant. This is the most crucial building
317 block of the rounding error analysis for any variant of HQR because the \mathbf{R} factor is formed by
318 applying the HH transformations to \mathbf{A} and the \mathbf{Q} factor is formed by applying them in reverse
319 order to the identity. Both of the blocked versions in [subsection 3.2](#) and [subsection 3.3](#) also require
320 slightly different but efficient implementations of this step. For example, BQR in [alg. 5](#) uses level-3
321 BLAS operations to apply multiple HH transformations at once whereas the variant of HQR in
322 [alg. 3](#) can only use level-2 BLAS operations to apply HH transformations.

323 A HH transformation is applied through a series of inner and outer products, since HH matrices
324 are rank-1 updates of the identity. That is, computing $\mathbf{P}_\mathbf{v}\mathbf{x}$ for any $\mathbf{x} \in \mathbb{R}^m$ is as simple as computing

$$325 \quad (3.8) \quad \mathbf{y} := \mathbf{P}_\mathbf{v}\mathbf{x} = \mathbf{x} - (\beta\mathbf{v}^\top\mathbf{x})\mathbf{v}.$$

326 Let us assume that \mathbf{x} is an exact vector and there were errors incurred in forming \mathbf{v} and β . The
327 errors incurred from computing \mathbf{v} and β need to be included in addition to the new rounding
328 errors accumulating from the action of applying $\mathbf{P}_\mathbf{v}$ to a column. In practice, \mathbf{x} is any column in
329 $\mathbf{A}^{(i-1)}[i+1 : m, i+1 : n]$, where the superscript $(i-1)$ indicates that this submatrix of \mathbf{A} has
330 already been transformed by $i-1$ HH transformations that zeroed out components below $\mathbf{A}[j, j]$
331 for $j = 1 : i-1$. We show the error for forming $\hat{\mathbf{w}}$ where $\mathbf{w} := \beta\mathbf{v}^\top\mathbf{x}\mathbf{v}$ and $\mathbf{v}, \mathbf{x} \in \mathbb{R}^m$,

$$332 \quad \hat{\mathbf{w}} = \text{fl}(\hat{\beta} \text{fl}(\hat{\mathbf{v}}^\top\mathbf{x})\hat{\mathbf{v}}) = (1+\theta_m)(1+\delta)(1+\delta')(\beta + \Delta\beta)(\mathbf{v} + \Delta\mathbf{v})^\top\mathbf{x}(\mathbf{v} + \Delta\mathbf{v}),$$

333 where θ_m is from computing the inner product $\hat{\mathbf{v}}^\top\mathbf{x}$, and δ and δ' are from multiplying β , $\text{fl}(\hat{\mathbf{v}}^\top\mathbf{x})$,
334 and $\hat{\mathbf{v}}$. The forward error is

$$335 \quad \hat{\mathbf{w}} = \mathbf{w} + \Delta\mathbf{w}, \quad |\Delta\mathbf{w}| \leq \tilde{\gamma}_m|\beta||\mathbf{v}|^\top|\mathbf{x}||\mathbf{v}|.$$

336 Subtracting $\hat{\mathbf{w}}$ from \mathbf{x} yields the HH transformation with forward error,

$$337 \quad (3.9) \quad \text{fl}(\hat{\mathbf{P}}_\mathbf{v}\mathbf{x}) = \text{fl}(\mathbf{x} - \hat{\mathbf{w}}) = (1+\delta)(\mathbf{x} - \mathbf{w} - \Delta\mathbf{w}) = \mathbf{y} + \Delta\mathbf{y} = (\mathbf{P}_\mathbf{v} + \Delta\mathbf{P}_\mathbf{v})\mathbf{x},$$

338 where $|\Delta\mathbf{y}| \leq u|\mathbf{x}| + \tilde{\gamma}_m|\beta||\mathbf{v}||\mathbf{v}|^\top|\mathbf{x}|$. Using $\sqrt{2/\beta} = \|\mathbf{v}\|_2$, we form a normwise bound,

$$339 \quad (3.10) \quad \|\Delta\mathbf{y}\|_2 \leq \tilde{\gamma}_m\|\mathbf{x}\|_2.$$

Next, we convert this to a backward error for \mathbf{P}_v . Since $\Delta\mathbf{P}_v$ is exactly $\frac{1}{\mathbf{x}^\top \mathbf{x}} \Delta\mathbf{y} \mathbf{x}^\top$, we can compute its Frobenius norm by using $\Delta\mathbf{P}_v[i, j] = \frac{1}{\|\mathbf{x}\|_2^2} \Delta\mathbf{y}[i] \mathbf{x}[j]$,

$$(3.11) \quad \|\Delta\mathbf{P}_v\|_F = \left(\sum_{i=1}^m \sum_{j=1}^m \left(\frac{1}{\|\mathbf{x}\|_2^2} \Delta\mathbf{y}[i] \mathbf{x}[j] \right)^2 \right)^{1/2} = \frac{\|\Delta\mathbf{y}\|_2}{\|\mathbf{x}\|_2} \leq \tilde{\gamma}_m,$$

where the last inequality is a direct application of (3.10).

Applying many successive HH transformations. Consider applying a sequence of transformations in the set $\{\mathbf{P}_i\}_{i=1}^r \subset \mathbb{R}^{m \times m}$ to $\mathbf{x} \in \mathbb{R}^m$, where \mathbf{P}_i 's are all HH transformations computed with $\tilde{\mathbf{v}}_i$'s and $\hat{\beta}_i$'s. This is directly applicable to HQR as $\mathbf{Q} = \mathbf{P}_1 \cdots \mathbf{P}_n \mathbf{I}$ and $\mathbf{R} = \mathbf{Q}^\top \mathbf{A} = \mathbf{P}_n \cdots \mathbf{P}_1 \mathbf{A}$. Lemma 3.2 is very useful for any sequence of transformations, where each transformation has a known bound. We will invoke this lemma to prove Lemma 3.3, and use it in future sections for other consecutive transformations.

LEMMA 3.2. If $\mathbf{X}_j + \Delta\mathbf{X}_j \in \mathbb{R}^{m \times m}$ satisfies $\|\Delta\mathbf{X}_j\|_F \leq \delta_j \|\mathbf{X}_j\|_2$ for all j , then

$$\left\| \prod_{j=1}^n (\mathbf{X}_j + \Delta\mathbf{X}_j) - \prod_{j=1}^n \mathbf{X}_j \right\|_F \leq \left(-1 + \prod_{j=1}^n (1 + \delta_j) \right) \prod_{j=1}^n \|\mathbf{X}_j\|_2.$$

LEMMA 3.3. Consider applying a sequence of transformations $\mathbf{Q} = \mathbf{P}_r \cdots \mathbf{P}_2 \mathbf{P}_1$ onto vector $\mathbf{x} \in \mathbb{R}^m$ to form $\hat{\mathbf{y}} = \mathbf{fl}(\hat{\mathbf{P}}_r \cdots \hat{\mathbf{P}}_2 \hat{\mathbf{P}}_1 \mathbf{x})$, where $\hat{\mathbf{P}}_k$'s are HH transformations constructed from $\hat{\beta}_k$ and $\hat{\mathbf{v}}_k$. These HH vectors and constants are computed via alg. 2 and the rounding errors are bounded by (3.5) and (3.7). If each transformation is computed via (3.8), then

$$(3.12) \quad \hat{\mathbf{y}} = \mathbf{Q}(\mathbf{x} + \Delta\mathbf{x}) = (\mathbf{Q} + \Delta\mathbf{Q})\mathbf{x} = \hat{\mathbf{Q}}\mathbf{x},$$

$$(3.13) \quad \|\Delta\mathbf{y}\|_2 \leq r\tilde{\gamma}_m \|\mathbf{x}\|_2, \quad \|\Delta\mathbf{Q}\|_F \leq r\tilde{\gamma}_m.$$

Proof. Applying Lemma 3.2 directly to \mathbf{Q} yields

$$(3.14) \quad \|\Delta\mathbf{Q}\|_F = \left\| \prod_{j=1}^r (\mathbf{P}_j + \Delta\mathbf{P}_j) - \prod_{j=1}^r \mathbf{P}_j \right\|_F \leq \left(-1 + \prod_{j=1}^r (1 + \tilde{\gamma}_{m-j+1}) \right) \prod_{j=1}^r \|\mathbf{P}_j\|_2 \leq -1 + (1 + \tilde{\gamma}_m)^r,$$

since \mathbf{P}_j 's are orthogonal and have 2-norm, 1, and $m - j + 1 \leq m$. While we omit the details here, we can show that $(1 + \tilde{\gamma}_m)^r - 1 \leq r\tilde{\gamma}_m$ using the argument from Lemma 2.1 if $r\tilde{\gamma}_m \leq 1/2$. \square

In this error analysis, the prevailing bound for errors at various stages of forming and applying a HH transformation is $\tilde{\gamma}_m$ where m corresponds to the dimension of the transformed vectors. In Lemma 3.3, a factor of r is introduced for applying r HH transformations to form the term $r\tilde{\gamma}_m \approx rmu$. Therefore, we can expect that the columnwise norm error for a thin QR factorization should be $\mathcal{O}(mnu)$ for a full rank matrix. In Theorem 3.4, we formalize this by applying Lemma 3.3 directly and also show a conversion of columnwise bounds to a matrix norm bound,

$$(3.15) \quad \|\Delta\mathbf{R}\|_F = \left(\sum_{i=1}^n \|\Delta\mathbf{R}[:, i]\|_2^2 \right)^{1/2} \leq \left(\sum_{i=1}^n n^2 \tilde{\gamma}_m^2 \|\mathbf{A}[:, i]\|_2^2 \right)^{1/2} = n\tilde{\gamma}_m \|\mathbf{A}\|_F.$$

We gather these results into Theorem 3.4.

369 THEOREM 3.4. Let $\mathbf{A} \in \mathbb{R}^{m \times n}$ with $m \geq n$ have full rank, n . Let $\hat{\mathbf{Q}} \in \mathbb{R}^{m \times n}$ and $\hat{\mathbf{R}} \in \mathbb{R}^{n \times n}$ be
 370 the thin QR factors of \mathbf{A} obtained via [alg. 3](#). Then,

$$\begin{aligned} 371 \quad \hat{\mathbf{R}} &= \mathbf{R} + \Delta\mathbf{R} = \text{fl}(\hat{\mathbf{P}}_n \cdots \hat{\mathbf{P}}_1 \mathbf{A}), \quad \|\Delta\mathbf{R}[:, j]\|_2 \leq n\tilde{\gamma}_m \|\mathbf{A}[:, j]\|_2, \quad \|\Delta\mathbf{R}\|_F \leq n\tilde{\gamma}_m \|\mathbf{A}\|_F \\ 372 \quad \hat{\mathbf{Q}} &= \mathbf{Q} + \Delta\mathbf{Q} = \text{fl}(\hat{\mathbf{P}}_1 \cdots \hat{\mathbf{P}}_n \mathbf{I}), \quad \|\Delta\mathbf{Q}[:, j]\|_2 \leq n\tilde{\gamma}_m, \quad \|\Delta\mathbf{Q}\|_F \leq n^{3/2}\tilde{\gamma}_m. \end{aligned}$$

374 Let $\mathbf{A} + \Delta\mathbf{A} = \hat{\mathbf{Q}}\hat{\mathbf{R}}$, where $\hat{\mathbf{Q}}$ and $\hat{\mathbf{R}}$ are obtained via [Algorithm 3](#). Then the backward error is

$$375 \quad \|\hat{\mathbf{Q}}\hat{\mathbf{R}} - \mathbf{A}\|_F \leq n^{3/2}\tilde{\gamma}_m \|\mathbf{A}\|_F.$$

376 Note that the last backward error result follows from the columnwise forward errors for $\hat{\mathbf{R}}$ and
 377 $\hat{\mathbf{Q}}$. Out of all of these different ways of measuring the error from computing a QR factorization
 378 (forward/backward errors for column/matrix norms), we will focus on $\|\hat{\mathbf{Q}} - \mathbf{Q}\|_F$, a measure of
 379 orthogonality of the \mathbf{Q} factor for the remainder of [section 3](#) and for [section 4](#). The numerical
 380 experiments in [section 5](#) measure backward and forward errors with $\|\hat{\mathbf{Q}}\hat{\mathbf{R}} - \mathbf{A}\|_F$ and $\|\hat{\mathbf{Q}}^\top \hat{\mathbf{Q}} - \mathbf{I}\|_2$.

381 The content of this section shows the standard rounding error analysis in [\[14\]](#) where some
 382 important stages are summarized in [\(3.5\)](#), [\(3.7\)](#), and [\(3.13\)](#), which we will modify to different
 383 mixed precision settings in [section 4](#). These quantities account for various forward and backward
 384 errors formed in computing essential components of HQR, namely the HH constant and vector, as
 385 well as normwise errors of the action of applying HH transformations. In the next sections, we
 386 present blocked variants of HQR that use [alg. 3](#).

387 **3.2. Block HQR with partitioned columns (BQR).** We refer to the blocked variant
 388 of HQR where the columns are partitioned as BQR. Note that this section relies on the WY
 389 representation described in [\[5\]](#) instead of the storage-efficient version of [\[21\]](#), even though both are
 390 known to be just as numerically stable as HQR.

391 **3.2.1. The WY Representation.** A convenient matrix representation that accumulates r
 392 HH reflectors is known as the WY representation (see [\[5, 11\]](#)). [Lemma 3.5](#) shows how to update
 393 a rank- j update of the identity, $\mathbf{Q}^{(j)}$, with a HH transformation, \mathbf{P} , to produce a rank- $(j+1)$
 394 update of the identity, $\mathbf{Q}^{(j+1)}$. With the correct initialization of \mathbf{W} and \mathbf{Y} , we can build the WY
 395 representation of successive HH transformations as shown in [Algorithm 4](#). This algorithm assumes
 396 that the HH vectors, \mathbf{V} , and constants, β , have already been computed. Since the \mathbf{Y} factor is
 397 exactly \mathbf{V} , we only need to compute the \mathbf{W} factor.

398 LEMMA 3.5. Suppose $\mathbf{X}^{(j)} = \mathbf{I} - \mathbf{W}^{(j)}\mathbf{Y}^{(j)\top} \in \mathbb{R}^{m \times m}$ is an orthogonal matrix with $\mathbf{W}^{(j)}, \mathbf{Y}^{(j)} \in$
 399 $\mathbb{R}^{m \times j}$. Let us define $\mathbf{P} = \mathbf{I} - \beta\mathbf{v}\mathbf{v}^\top$ for some $\mathbf{v} \in \mathbb{R}^m$ and let $\mathbf{z}^{(j+1)} = \beta\mathbf{X}^{(j)}\mathbf{v}$. Then,

$$400 \quad \mathbf{X}^{(j+1)} = \mathbf{X}^{(j)}\mathbf{P} = \mathbf{I} - \mathbf{W}^{(j+1)}\mathbf{Y}^{(j+1)\top},$$

401 where $\mathbf{W}^{(j+1)} = [\mathbf{W}^{(j)}|\mathbf{z}]$ and $\mathbf{Y}^{(j+1)} = [\mathbf{Y}^{(j)}|\mathbf{v}]$ are each m -by- $(j+1)$.

402 In HQR, \mathbf{A} is transformed into an upper triangular matrix \mathbf{R} by identifying a HH transformation
 403 that zeros out a column below the diagonal, then applying that HH transformation to the bottom
 404 right partition. For example, the k^{th} HH transformation finds an $m-k+1$ sized HH transformation
 405 that zeros out column k below the diagonal and then applies it to the $(m-k+1)$ -by- $(n-k)$
 406 partition of the matrix, $\mathbf{A}[k : m, k+1 : n]$. Since the $k+1^{\text{st}}$ column is transformed by the
 407 k^{th} HH transformation, this algorithm must be executed serially as shown in [alg. 3](#). The highest
 408 computational burden at each iteration falls on [alg. 3](#) line 6, which requires Level-2 BLAS operations
 409 when computed efficiently.

Algorithm 4: $\mathbf{W}, \mathbf{Y} \leftarrow \text{buildWY}(V, \beta)$: Given a set of householder vectors $\{\mathbf{V}[:, i]\}_{i=1}^r$ and their corresponding constants $\{\beta_i\}_{i=1}^r$, form the final \mathbf{W} and \mathbf{Y} factors of the WY representation of $\mathbf{P}_1 \cdots \mathbf{P}_r$, where $\mathbf{P}_i := \mathbf{I}_m - \beta_i \mathbf{v}_i \mathbf{v}_i^\top$

Input: $\mathbf{V} \in \mathbb{R}^{m \times r}$, $\beta \in \mathbb{R}^r$ where $m > r$.

Output: \mathbf{W}

```

1 Initialize:  $\mathbf{W} := \beta_1 \mathbf{V}[:, 1]$ . /*  $\mathbf{Y}$  is  $\mathbf{V}$ . */
2 for  $j = 2 : r$  do
3    $\mathbf{z} \leftarrow \beta_j [\mathbf{V}[:, j] - \mathbf{W} (\mathbf{V}[:, 1 : j-1]^\top \mathbf{V}[:, j])]$ 
4    $\mathbf{W} \leftarrow [\mathbf{W} \quad \mathbf{z}]$  /* Update  $\mathbf{W}$  to an  $m$ -by- $j$  matrix. */
5 return  $\mathbf{W}$ 
```

In contrast, BQR replaces this step with Level-3 BLAS operations by partitioning \mathbf{A} into blocks of columns. Let $\mathbf{A} = [\mathbf{C}_1 \cdots \mathbf{C}_N]$ where $\mathbf{C}_1, \dots, \mathbf{C}_{N-1}$ are each m -by- r , and \mathbf{C}_N holds the remaining columns. The k^{th} block, \mathbf{C}_k , is transformed with HQR (alg. 3), and the WY representation of these r successive HH transformations is constructed as in alg. 4. We write the WY update as

$$(3.14) \quad \mathbf{X}_k = \mathbf{I}_m - \mathbf{W}_k \mathbf{Y}_k^\top = \mathbf{P}_k^{(1)} \cdots \mathbf{P}_k^{(r)}.$$

Thus far, algs. 3 and 4 are rich in Level-2 BLAS operations. Next, $\mathbf{I} - \mathbf{Y}_k \mathbf{W}_k^\top$ is applied to $[\mathbf{C}_2 \cdots \mathbf{C}_N]$ with two Level-3 BLAS operations as shown in line 5 of alg. 5. BQR performs approximately $1 - \mathcal{O}(1/N)$ fraction of its FLOPs in Level-3 BLAS operations (see section 5.2.3 of [11]), and can reap the benefits from the accelerated block FMA feature of TensorCore. Note that BQR does require strictly more FLOPs when compared to HQR, but these additional FLOPs are negligible in standard precision and does not impact the numerical stability. A pseudocode for BQR is shown in alg. 5 where we assume that $n = Nr$ to make our error analysis in section 3.2.2 simple. In practice, an efficient implementation might require r to be a power of two or a product of small prime factors and result a thinner N^{th} block compared to the rest. This discrepancy is easily fixed by padding the matrix with zeros, a standard procedure for standard algorithms like the Fast Fourier Transform (FFT). For any variable $x \in \{\mathbf{X}, \mathbf{W}, \mathbf{Y}, \mathbf{z}, \beta, \mathbf{v}, \mathbf{P}\}$, $x_k^{(j)}$ corresponds to the j^{th} update for the k^{th} block.

3.2.2. BQR: Rounding Error Analysis. We now present the basic structure for the rounding error analysis for alg. 5, which consist of: 1)HQR, 2)building the \mathbf{W} factor, and 3) updating the remaining blocks with the WY representation. We have adapted the analysis from [14] to fit this exact variant, and denote $\hat{\mathbf{Q}}_{BQR}, \hat{\mathbf{R}}_{BQR}$ to be the outputs from alg. 5. First, we analyze the error accumulated from updating $\mathbf{X}_k^{(j-1)}$ to $\mathbf{X}_k^{(j)}$, which applies a rank-1 update via the subtraction of the outer product $\hat{\mathbf{z}}_k^{(j)} \hat{\mathbf{v}}_k^{(j)\top}$. Since $\mathbf{z}_k^{(j)} = \beta_k^{(j)} \mathbf{X}_k^{(j-1)} \mathbf{v}_k^{(j)}$, this update requires a single HH transformation on the right side in the same efficient implementation that is discussed in (3.8),

$$(3.15) \quad \hat{\mathbf{X}}_k^{(j)} = \hat{\mathbf{X}}_k^{(j-1)} - \text{fl}(\hat{\beta}_k^{(j-1)} \hat{\mathbf{X}}_k^{(j-1)} \hat{\mathbf{v}}_k^{(j-1)}) \hat{\mathbf{v}}_k^{(j)\top} = \hat{\mathbf{X}}_k^{(j-1)} (\mathbf{P}_k^{(j)} + \Delta \mathbf{P}_k^{(j)}),$$

where $\|\Delta \mathbf{P}_k^{(j)}\|_F \leq \tilde{\gamma}_{m-(k-1)r}$. Since $\hat{\mathbf{X}}_k^{(1)} = \mathbf{I} - \hat{\beta}_k^{(1)} \hat{\mathbf{v}}_k^{(1)} \hat{\mathbf{v}}_k^{(1)\top} = \mathbf{P}_k^{(1)} + \Delta \mathbf{P}_k^{(1)}$, we can travel up the recursion relation in (3.15) and use Lemma 3.2 to find

$$(3.16) \quad \|\Delta \mathbf{X}_k^{(j)}\|_F \leq \tilde{\gamma}_{m-(k-1)r}.$$

Algorithm 5: $\mathbf{Q}, \mathbf{R} \leftarrow \text{blockHQR}(\mathbf{A}, r)$: Perform HH QR factorization of matrix \mathbf{A} with column partitions of size r .

Input: $\mathbf{A} \in \mathbb{R}^{m \times n}$, $r \in \mathbb{R}$ where $r < n$.
Output: \mathbf{Q}, \mathbf{R}

```

1  $N = \frac{n}{r}$ 
  // Let  $\mathbf{A} = [\mathbf{C}_1 \cdots \mathbf{C}_N]$  where all blocks except  $\mathbf{C}_N$  are  $m$ -by- $r$  sized.
2 for  $i = 1 : N$  do
3    $\mathbf{V}_i, \beta_i, \mathbf{C}_i \leftarrow \text{hhQR}(\mathbf{C}_i)$                                      /* Algorithm 3 */
4    $\mathbf{W}_i \leftarrow \text{buildWY}(\mathbf{V}_i, \beta_i)$                                    /* Algorithm 4 */
5    $[\mathbf{C}_{i+1} \cdots \mathbf{C}_N] \leftarrow \mathbf{V}_i (\mathbf{W}_i^\top [\mathbf{C}_{i+1} \cdots \mathbf{C}_N])$  /* update the rest: BLAS-3 */
  //  $\mathbf{A}$  has been transformed into  $\mathbf{R} = \mathbf{Q}^\top \mathbf{A}$ .
  // Now build  $\mathbf{Q}$  using level-3 BLAS operations.
6  $\mathbf{Q} \leftarrow \mathbf{I}$                                                          /*  $\mathbf{I}_m$  if full QR, and  $\mathbf{I}_{m \times n}$  if thin QR. */
7 for  $i = N : -1 : 1$  do
8    $\mathbf{Q}[(i-1)r+1 : m, (i-1)r+1 : n] \leftarrow \mathbf{W}_i (\mathbf{V}_i^\top \mathbf{Q}[(i-1)r+1 : m, (i-1)r+1 : n])$ 
9 return  $\mathbf{Q}, \mathbf{A}$ 
```

438 *HQR within each block: line 3 of alg. 5.* We apply Algorithm 3 to the k^{th} block, $\hat{\mathbf{X}}_{k-1} \cdots \hat{\mathbf{X}}_1 \mathbf{C}_k$,
 439 which applies r more HH transformations to columns that had been transformed by $(k-1)$ WY
 440 transformations in prior iterations. The upper trapezoidal factor that results from applying HQR
 441 to $\mathbf{C}_k^{((k-1)r)}$ corresponds to the $(k-1)r+1^{\text{st}}$ to kr^{th} columns of $\hat{\mathbf{R}}_{BQR}$, and applying Lemmas 3.2
 442 and 3.3 yields

$$443 \quad \|\hat{\mathbf{R}}_{BQR}[:, j] - \mathbf{R}[:, j]\|_2 \leq r\tilde{\gamma}_m \|\hat{\mathbf{X}}_{k-1} \cdots \hat{\mathbf{X}}_1^\top \mathbf{C}_k[:, j]\|_2, \quad j = (k-1)r+1 : kr.$$

444 *Build WY at each block: line 4 of alg. 5.* We now calculate the rounding errors incurred from
 445 building the WY representation when given a set of HH vectors and constants as shown in alg. 4.
 446 Since the columns of $\hat{\mathbf{Y}}_k$ are simply $\{\hat{\mathbf{v}}_k^{(j)}\}$ built in alg. 3 the errors for forming these are shown in
 447 (3.5) where m should be replaced by $m - (k-1)r$. The HH constants, $\hat{\beta}_k^{(j)}$ are bounded by (3.7)
 448 modified similarly. Thus, $\mathbf{z}_k^{(j)}$ is the only newly computed quantity. Using (3.5), (3.7), and (3.16),
 449 we find

$$\begin{aligned}
 450 \quad \|\Delta \mathbf{z}_k^{(j)}\|_2 &= \|\Delta \mathbf{X}_k^{(j-1)} \hat{\beta}_k^{(j)} \hat{\mathbf{v}}_k^{(j)}\|_2 \leq \|\Delta \mathbf{X}_k^{(j-1)}\|_2 \|\hat{\beta}_k^{(j)} \hat{\mathbf{v}}_k^{(j)}\|_2 \\
 451 \quad &\leq \|\Delta \mathbf{X}_k^{(j-1)}\|_F \|\hat{\beta}_k^{(j)} \hat{\mathbf{v}}_k^{(j)}\|_2 \\
 452 \quad &\leq ((1 + (j-1)\tilde{\gamma}_{m-(k-1)r})(1 + \tilde{\gamma}_{m-(k-1)r}) - 1) \|\beta_k^{(j)} \mathbf{v}_k^{(j)}\|_2 \\
 453 \quad &\leq j\tilde{\gamma}_{m-(k-1)r} \|\mathbf{z}_k^{(j)}\|_2
 \end{aligned}$$

455 Componentwise bounds follow immediately, and are summarized in Lemma 3.6.

456 **LEMMA 3.6.** *Consider the construction of the WY representation for the k^{th} partition of matrix*

457 $\mathbf{A} \in \mathbb{R}^{m \times n}$ given a set of HH constants and vectors, $\{\beta_k^{(j)}\}_{j=1}^r$ and $\{\mathbf{v}_k^{(j)}\}$ via [alg. 4](#). Then,

458 (3.17) $\hat{\mathbf{z}}_k^{(j)} = \mathbf{z}_k^{(j)} + \Delta \mathbf{z}_k^{(j)}, \quad |\Delta \mathbf{z}_k^{(j)}| \leq j \tilde{\gamma}_{m-(k-1)r} |\mathbf{z}_k^{(j)}|$

459 (3.18) $\hat{\mathbf{v}}_k^{(j)} = \mathbf{v}_k^{(j)} + \Delta \mathbf{v}_k^{(j)}, \quad |\Delta \mathbf{v}_k^{(j)}| \leq \tilde{\gamma}_{m-(k-1)r} |\mathbf{v}_k^{(j)}|,$

461 where the second bound is derived from (3.5).

462 Most importantly, this shows that constructing the WY update is just as numerically stable as
463 applying successive HH transformations (see Section 19.5 of [14]).

464 *Update blocks to the right: line 5 of alg. 5.* We now consider applying $\mathbf{X}_k := \mathbf{I} - \mathbf{W}_k \mathbf{Y}_k^\top$ to
465 some matrix, \mathbf{B} . In practice, \mathbf{B} is the bottom right submatrix, $[\mathbf{C}_{k+1} \cdots \mathbf{C}_N][(k-1)r+1 : m, :]$.
466 We can apply (3.16) directly to the columns of \mathbf{B} ,

467 (3.19) $\|\mathbf{fl}(\hat{\mathbf{X}}_k \mathbf{B}[:, j])\|_2 = \|\mathbf{fl}(\hat{\mathbf{X}}_k^{(r)} \mathbf{B}[:, j])\|_2 \leq r \tilde{\gamma}_{m-(k-1)r} \|\mathbf{B}[:, j]\|_2$

469 A normwise bound for employing a general matrix-matrix multiplication operation is stated in
470 section 19.5 of [14].

471 *Multiple WY updates: line 8-9 of alg. 5.* All that remains is to consider the application of
472 successive WY updates to form the QR factorization computed with BQR denoted as \mathbf{Q}_{BQR} and
473 \mathbf{R}_{BQR} . We can apply [Lemma 3.2](#) directly by setting $\mathbf{X}_k := \mathbf{I} - \mathbf{W}_k \mathbf{Y}_k^\top$ and consider the backward
474 errors for applying the sequence to a vector, $\mathbf{x} \in \mathbb{R}^m$, as we did for [Lemma 3.3](#). Since $\mathbf{X}_k =$
475 $\mathbf{P}_{(k-1)r+1} \cdots \mathbf{P}_{kr}$, is simply a sequence of HH transformations, it is orthogonal, i.e. $\|\mathbf{X}_k\|_2 = 1$. We
476 only need to replace with \mathbf{x} with $\mathbf{A}[:, i]$'s to form the columnwise bounds for \mathbf{R}_{BQR} , and apply the
477 transpose to $\hat{\mathbf{e}}_i$'s to form the bounds for \mathbf{Q}_{BQR} . Then,

478 (3.20) $\left\| \prod_{k=1}^N (\mathbf{X}_k + \Delta \mathbf{X}_k) - \prod_{k=1}^N \mathbf{X}_k \right\|_F \leq \left(-1 + \sum_{k=1}^N (1 + r \tilde{\gamma}_{m-(k-1)r}) \right) \leq rN \tilde{\gamma}_m \equiv n \tilde{\gamma}_m,$

479 (3.21) $\|\hat{\mathbf{Q}}_{BQR} - \mathbf{Q}\|_F \leq n^{3/2} \tilde{\gamma}_m.$

481 We can also form the normwise bound for the j' th column of $\hat{\mathbf{Q}}_{BQR}, \hat{\mathbf{R}}_{BQR}$. If we let $k' = \lceil j'/r \rceil^{th}$,
482 then the j' th column is the result of applying $k'-1$ WY updates and an additional HQR. Applying
483 [Lemma 3.2](#) yields

484 (3.22) $\|\Delta \mathbf{R}_{BQR}[:, j']\|_2 \leq r k' \tilde{\gamma}_m \|\mathbf{A}[:, j]\|_2$

485 (3.23) $\|\Delta \mathbf{Q}_{BQR}[:, j']\|_2 \leq r k' \tilde{\gamma}_m$

487 and near orthogonality of the \mathbf{Q} factor is still achieved,

488 (3.24) $\|\Delta \mathbf{Q}_{BQR}\|_F = r \tilde{\gamma}_m \sum_{j=1}^n \lceil j/r \rceil = n^{3/2} \tilde{\gamma}_m.$

489 The primary goal of the analysis presented in this section is to provide the basic skeleton for the
490 standard BQR rounding error analysis to make the generalization to mixed precision settings in
491 [section 4](#) easier. Readers should refer to [11, 14] for full details.

3.3. Block HQR with partitioned rows : Tall-and-Skinny QR (TSQR). Some important problems that require QR factorizations of overdetermined systems include least squares problems, eigenvalue problems, low rank approximations, as well as other matrix decompositions. Although Tall-and-Skinny QR (TSQR) broadly refers to block QR factorization methods with row partitions, we will discuss a specific variant of TSQR which is also known as the AllReduce algorithm [20]. In this paper, the TSQR/AllReduce algorithm refers to the most parallel variant of the block QR factorization algorithms discussed in [10]. A detailed description and rounding error analysis of this algorithm can be found in [20], and we present a pseudocode for the algorithm in [alg. 6](#). Our initial interest in this algorithm came from its parallelizable nature, which is particularly suitable to implementation on GPUs. Additionally, our numerical simulations (discussed in [section 5](#)) show that TSQR can not only increase the speed but also outperform the traditional HQR factorization in low precisions.

3.3.1. TSQR/AllReduce Algorithm. [Algorithm 6](#) partitions the rows of a tall-and-skinny matrix, \mathbf{A} . HQR is performed on each of those blocks and pairs of \mathbf{R} factors are combined to form the next set of \mathbf{A} matrices to be QR factorized. This process is repeated until only a single \mathbf{R} factor remains, and the \mathbf{Q} factor is built from all of the HH constants and vectors stored at each level. The most gains from parallelization can be made in the initial level where the maximum number of independent HQR factorizations occur. Although more than one configuration of this algorithm may be available for a given tall-and-skinny matrix, the number of nodes available and the shape of the matrix eliminate some of those choices. For example, a 1600-by-100 matrix can be partitioned into 2, 4, 8, or 16 initial row-blocks but may be restricted by a machine with only 4 nodes, and a 1600-by-700 matrix can only be partitioned into 2 initial blocks. Our numerical experiments show that the choice in the initial partition, which directly relates to the recursion depth of TSQR, has an impact in the accuracy of the QR factorization.

We refer to *level* as the number of recursions in a particular TSQR implementation. An L -level TSQR algorithm partitions the original matrix into $2^{(L)}$ submatrices in the initial or 0^{th} level of the algorithm, and 2^{L-i} QR factorizations are performed in level i for $i = 1, \dots, L$. The set of matrices that are QR factorized at each level i are called $\mathbf{A}_j^{(i)}$ for $j = 1, \dots, 2^{L-i}$, where superscript (i) corresponds to the level and the subscript j indexes the row-blocks within level i . In the following sections, [alg. 6](#) (`tsqr`) will find a TSQR factorization of a matrix $A \in \mathbb{R}^{m \times n}$ where $m \gg n$. The inline function `qr` refers to [alg. 3](#) and we use [alg. 2](#) as a subroutine of `qr`.

TSQR Notation. We introduce new notation due to the multi-level nature of the TSQR algorithm. In the final task of constructing \mathbf{Q} , $\mathbf{Q}_j^{(i)}$ factors are aggregated from each block at each level. Each $\mathbf{Q}_j^{(i)}$ factor from level i is partitioned such that two corresponding $\mathbf{Q}^{(i-1)}$ factors from level $i-1$ can be applied to them. The partition (approximately) splits $\mathbf{Q}_j^{(i)}$ into two halves, $[\tilde{\mathbf{Q}}_{j,1}^{(i)\top} \tilde{\mathbf{Q}}_{j,2}^{(i)\top}]^\top$. The functions $\alpha(j)$ and $\phi(j)$ are defined such that $\mathbf{Q}_j^{(i)}$ is applied to the correct blocks from the level below: $\tilde{\mathbf{Q}}_{\alpha(j),\phi(j)}^{(i+1)}$. For $j = 1, \dots, 2^{L-i}$ at level i , we need $j = 2(\alpha(j) - 1) + \phi(j)$, where $\alpha(j) = \lceil \frac{j}{2} \rceil$ and $\phi(j) = 2 + j - 2\alpha(j) \in \{1, 2\}$. [section 3.3.2](#) shows full linear algebra details for a single-level ($L = 1, 2$ initial blocks) example. The reconstruction of \mathbf{Q} can be implemented more efficiently (see

531 [4]), but the reconstruction method in [alg. 6](#) is presented for a clear, straightforward explanation.

Algorithm 6: $\mathbf{Q}, \mathbf{R} = \text{tsqr}(\mathbf{A}, L)$. Finds a QR factorization of a tall, skinny matrix, \mathbf{A} .

Input: $\mathbf{A} \in \mathbb{R}^{m \times n}$ where $m \gg n$, $L \leq \lfloor \log_2(\frac{m}{n}) \rfloor$, and 2^L is the initial number of blocks.

Output: $\mathbf{Q} \in \mathbb{R}^{m \times n}$, $\mathbf{R} \in \mathbb{R}^{n \times n}$ such that $\mathbf{QR} = \mathbf{A}$.

```

1  $h \leftarrow m2^{-L}$  // Number of rows.
/* Split  $\mathbf{A}$  into  $2^L$  blocks. Note that level  $(i)$  has  $2^{L-i}$  blocks. */
2 for  $j = 1 : 2^L$  do
3    $\mathbf{A}_j^{(0)} \leftarrow \mathbf{A}[(j-1)h + 1 : jh, :]$ 

/* Store HH vectors as columns of matrix  $\mathbf{V}_j^{(i)}$ , HH constants as components of
vector  $\beta_j^{(i)}$ , and set up the next level. */
4 for  $i = 0 : L - 1$  do
/* The inner loop can be parallelized. */
5   for  $j = 1 : 2^{L-i}$  do
6      $\mathbf{V}_{2j-1}^{(i)}, \beta_{2j-1}^{(i)}, \mathbf{R}_{2j-1}^{(i)} \leftarrow \text{qr}(\mathbf{A}_{2j-1}^{(i)})$ 
7      $\mathbf{V}_{2j}^{(i)}, \beta_{2j}^{(i)}, \mathbf{R}_{2j}^{(i)} \leftarrow \text{qr}(\mathbf{A}_{2j}^{(i)})$ 
532 8      $\mathbf{A}_j^{(i+1)} \leftarrow \begin{bmatrix} \mathbf{R}_{2j-1}^{(i)} \\ \mathbf{R}_{2j}^{(i)} \end{bmatrix}$ 

9    $\mathbf{V}_1^{(L)}, \beta_1^{(L)}, \mathbf{R} \leftarrow \text{qr}(\mathbf{A}_1^{(L)})$  // The final  $\mathbf{R}$  factor is built.
10   $\mathbf{Q}_1^{(L)} \leftarrow \text{hh\_mult}(\mathbf{V}_1^{(L)}, I_{2n \times n})$ 
/* Compute  $\mathbf{Q}^{(i)}$  factors by applying  $\mathbf{V}^{(i)}$  to  $\mathbf{Q}^{(i+1)}$  factors. */
11 for  $i = L - 1 : -1 : 1$  do
12   for  $j = 1 : 2^{L-i}$  do
13      $\mathbf{Q}_j^{(i)} \leftarrow \text{hh\_mult} \left( \mathbf{V}_j^{(i)}, \begin{bmatrix} \tilde{\mathbf{Q}}_{\alpha(j), \phi(j)}^{(i+1)} \\ \mathbf{0} \end{bmatrix} \right)$ 

14  $\mathbf{Q} \leftarrow []$ ; // Construct the final  $\mathbf{Q}$  factor.
15 for  $j = 1 : 2^L$  do
16    $\mathbf{Q} \leftarrow \begin{bmatrix} \mathbf{Q} \\ \text{hh\_mult} \left( \mathbf{V}_j^{(0)}, \begin{bmatrix} \tilde{\mathbf{Q}}_{\alpha(j), \phi(j)}^{(1)} \\ \mathbf{0} \end{bmatrix} \right) \end{bmatrix}$ 
17 return  $\mathbf{Q}, \mathbf{R}$ 

```

533 **3.3.2. Single-level Example.** In the single-level version of this algorithm, we first bisect \mathbf{A}
534 into $\mathbf{A}_1^{(0)}$ and $\mathbf{A}_2^{(0)}$ and compute the QR factorization of each of those submatrices. We combine the
535 resulting upper-triangular matrices (see below) which is QR factorized, and the process is repeated:

$$536 \quad \mathbf{A} = \begin{bmatrix} \mathbf{A}_1^{(0)} \\ \mathbf{A}_2^{(0)} \end{bmatrix} = \begin{bmatrix} \mathbf{Q}_1^{(0)} \mathbf{R}_1^{(0)} \\ \mathbf{Q}_2^{(0)} \mathbf{R}_2^{(0)} \end{bmatrix} = \begin{bmatrix} \mathbf{Q}_1^{(0)} & \mathbf{0} \\ \mathbf{0} & \mathbf{Q}_2^{(0)} \end{bmatrix} \begin{bmatrix} \mathbf{R}_1^{(0)} \\ \mathbf{R}_2^{(0)} \end{bmatrix} = \begin{bmatrix} \mathbf{Q}_1^{(0)} & \mathbf{0} \\ \mathbf{0} & \mathbf{Q}_2^{(0)} \end{bmatrix} \mathbf{A}_1^{(1)} = \begin{bmatrix} \mathbf{Q}_1^{(0)} & \mathbf{0} \\ \mathbf{0} & \mathbf{Q}_2^{(0)} \end{bmatrix} \mathbf{Q}_1^{(1)} \mathbf{R}.$$

537 The \mathbf{R} factor of $\mathbf{A}_1^{(1)}$ is the final \mathbf{R} factor of the QR factorization of the original matrix, \mathbf{A} . However,
538 the final \mathbf{Q} still needs to be constructed. Bisecting $\mathbf{Q}_1^{(1)}$ into two submatrices, i.e. $\tilde{\mathbf{Q}}_{1,1}^{(1)}$ and $\tilde{\mathbf{Q}}_{1,2}^{(1)}$,

allows us to write and compute the product more compactly,

$$\mathbf{Q} := \begin{bmatrix} \mathbf{Q}_1^{(0)} & \mathbf{0} \\ \mathbf{0} & \mathbf{Q}_2^{(0)} \end{bmatrix} \mathbf{Q}_1^{(1)} = \begin{bmatrix} \mathbf{Q}_1^{(0)} & \mathbf{0} \\ \mathbf{0} & \mathbf{Q}_2^{(0)} \end{bmatrix} \begin{bmatrix} \tilde{\mathbf{Q}}_{1,1}^{(1)} \\ \tilde{\mathbf{Q}}_{1,2}^{(1)} \end{bmatrix} = \begin{bmatrix} \mathbf{Q}_1^{(0)} \tilde{\mathbf{Q}}_{1,1}^{(1)} \\ \mathbf{Q}_2^{(0)} \tilde{\mathbf{Q}}_{1,2}^{(1)} \end{bmatrix}.$$

More generally, [alg. 6](#) takes a tall-and-skinny matrix \mathbf{A} and level L and finds a QR factorization by initially partitioning \mathbf{A} into $2^{(l)}$ row-blocks and includes the building of \mathbf{Q} . For simplicity, we assume that m is exactly $h2^{(l)}$ so that the initial partition yields $2^{(l)}$ blocks of equal sizes, h -by- n . Also, note that `hh_mult` refers to the action of applying multiple HH transformations given a set of HH vectors and constants, which can be performed by iterating line 6 of [alg. 3](#). This step can be done in a level-3 BLAS operation via a WY update if [alg. 6](#) was modified to store the WY representation at the QR factorization of each block of each level, $\mathbf{A}_j^{(i)}$.

3.3.3. TSQR: Rounding Error Analysis. The TSQR algorithm presented in [alg. 6](#) is a divide-and-conquer strategy for the QR factorization that uses the HQR within the subproblems. Divide-and-conquer methods can naturally be implemented in parallel and accumulate less rounding errors. For example, the single-level TSQR decomposition of a tall-and-skinny matrix, \mathbf{A} requires 3 total HQRs of matrices of sizes $\lfloor \log_2(\frac{m}{n}) \rfloor$ -by- n , $\lceil \log_2(\frac{m}{n}) \rceil$ -by- n , and $2n$ -by- n . The single-level TSQR strictly uses more FLOPs, but the dot product subroutines may accumulate smaller rounding errors (and certainly have smaller upper bounds) since they are performed on shorter vectors, and lead to a more accurate solution overall. These concepts are elucidated in [\[20\]](#) and we summarize the main results in [Theorem 3.7](#).

THEOREM 3.7. *Let $\mathbf{A} \in \mathbb{R}^{m \times n}$ with $m \geq n$ have full rank, n , and $\hat{\mathbf{Q}} \in \mathbb{R}^{m \times n}$ and $\hat{\mathbf{R}} \in \mathbb{R}^{n \times n}$ be the thin QR factors of \mathbf{A} obtained via [alg. 6](#) with L levels. Let us further assume that m is divisible by 2^L and $n\tilde{\gamma}_{m2^{-L}}, n\tilde{\gamma}_{2n} \ll 1$. Then, normwise error bounds for the j^{th} column ($j = 1 : n$) are*

$$(3.25) \quad \|\hat{\mathbf{R}}_{TSQR}[:, j] - \mathbf{R}[:, j]\|_2 \leq n(\tilde{\gamma}_{m2^{-L}} + L\tilde{\gamma}_{2n})\|\mathbf{A}[:, j]\|_2,$$

$$(3.26) \quad \|\hat{\mathbf{Q}}_{TSQR}[:, j] - \mathbf{Q}[:, j]\|_2 \leq n(\tilde{\gamma}_{m2^{-L}} + L\tilde{\gamma}_{2n}).$$

Note that the $n\tilde{\gamma}_{m2^{-L}}$ and $n\tilde{\gamma}_{2n}$ terms correspond to errors from applying HQR to the blocks in the initial partition and to the blocks in levels 1 through L respectively. We can easily replace these with analogous mixed precision terms and keep the analysis accurate. Both level-2 and level-3 BLAS implementations will be considered in [section 4](#).

4. Mixed precision error analysis. In this section, we consider three different mixed precision settings for the QR factorization, all of which take in a matrix \mathbf{A} stored in low precision and return \mathbf{Q}, \mathbf{R} both represented in low precision. First, we consider a trivial mixed precision setting where HQR, BQR, and TSQR are computed in high precision after casting up the input matrix at the beginning, and casting down the resulting high precision factors to low precision. Then in [subsection 4.1](#), we modify BQR and TSQR to utilize level-3 BLAS operations and TensorCore bFMAs for the matrix product subroutines. Finally, we impose [Assumption 2.3](#) in [subsection 4.2](#) to see how a mixed precision inner product impacts HQR, BQR, and TSQR when applied in level-2 BLAS operations.

Backward error of casting down vectors. First, consider casting down a vector $\mathbf{x} \in \mathbb{F}_h^{(m)}$. The componentwise forward error is,

$$\text{castdown}_l(\mathbf{x}) = \mathbf{x} + \Delta\mathbf{x}, \quad |\Delta\mathbf{x}| < u^{(l)}|\mathbf{x}|.$$

We use this to represent the backward error of a casting down a vector with a linear transformation, $\mathbf{I}^{(l)} := \mathbf{I} + \mathbf{E} \in \mathbb{R}^{m \times m}$, a diagonal perturbation of the identity. We write,

$$(4.1) \quad \mathbf{x}^{(l)} := \text{castdown}(\mathbf{x}^{(h)}) = \mathbf{I}^{(l)} \mathbf{x}^{(h)} = (\mathbf{I} + \mathbf{E}) \mathbf{x}^{(h)} = \mathbf{x}^{(h)} + \Delta \mathbf{x},$$

where $|\Delta \mathbf{x}| \leq u^{(l)} |\mathbf{x}^{(h)}|$ and $\|\Delta \mathbf{x}\|_2 \leq u^{(l)} \|\mathbf{x}^{(h)}\|_2$. Thus, $\mathbf{E} = \Delta \mathbf{x} \mathbf{x}^\top / \|\mathbf{x}\|_2^2$ and we can use the same argument as in (3.11) to form a backward matrix norm bound,

$$(4.2) \quad \|\mathbf{E}\|_F \leq u^{(l)}.$$

Casting down after HQR in high precision. Let us consider the trivial case of carrying out HQR in high precision and casting down at the very end. This is useful in for the analysis of mixed precision block algorithms as will be shown in subsections 4.1 and 4.2. If the two floating point types \mathbb{F}_l and \mathbb{F}_h satisfy $\mathbb{F}_l \subseteq \mathbb{F}_h$ and the matrix to be factorized is stored with low precision numbers, $\mathbf{A} \in \mathbb{F}_l^{m \times n}$, then casting up adds no rounding errors. Therefore, we can directly apply the analysis that culminated in Theorem 3.4, and we only consider the columnwise forward error in the \mathbf{Q} factor. Then, the j^{th} column of $\hat{\mathbf{Q}}_{HQR} = \mathbf{Q} + \Delta \mathbf{Q}_{HQR}$ is bounded normwise via $\|\Delta \mathbf{Q}_{HQR}[:, j]\|_2 \leq n \tilde{\gamma}_m^h$, and incurs an extra rounding error when $\hat{\mathbf{Q}}_{HQR} \in \mathbb{F}_h^{m \times n}$ is cast down to $\mathbb{F}_l^{m \times n}$.

Using this in Lemma 3.2 to analyze the forward norm error for the j^{th} column of the \mathbf{Q} factor computed with alg. 3 yields

$$(4.3) \quad \|(\text{castdown}(\hat{\mathbf{Q}}_{HQR}) - \mathbf{Q})[:, j]\|_2 = \|(\mathbf{I}^{(l)} \hat{\mathbf{P}}_1 \cdots \hat{\mathbf{P}}_n - \mathbf{P}_1 \cdots \mathbf{P}_n) \hat{\mathbf{e}}_j\|_2 \leq u^{(l)} + n \tilde{\gamma}_m^{(h)} + n u^{(l)} \tilde{\gamma}_m^{(h)}.$$

The final castdown operation increases the upper bound by $u^{(l)}$ and the size of \mathbf{A} has no impact on this extra rounding error. Applying this trivial mixed precision setting to BQR and TSQR would simply increase the error bound by approximately $u^{(l)}$ all the while taking an even longer time than the high precision implementation due the extra cast down and cast up operations. Therefore, we do not analyze the rounding error analysis of this mixed precision variant of BQR and TSQR. However, we will use this mixed precision HQR as a subroutine of the mixed precision BQR and TSQR in the following section.

4.1. Round down at block-level (BLAS-3). The mixed precision setting in this section is designed to meet the below requirements.

1. Modify Algorithms 5 and 6 to maximize level-3 BLAS operations and use TensorCore bFMAs.
2. Apply (4.3) to all instances of HQR to the error analyses for BQR and TSQR in section 3.
3. Cast down quantities at every block/level and the insertion of low precision errors $u^{(l)}$ should be somewhat correlated to the number of blocks and levels.
4. Both input and output of the various QR factorization algorithms are given in the low precision.

TensorCore's bFMA computes

$$(4.4) \quad \hat{\mathbf{D}} = \text{fl}_{TC}(\mathbf{C} + \mathbf{A}\mathbf{B}), \quad \mathbf{C}, \mathbf{D} \in \mathbb{F}_{\text{fp16}}^{4 \times 4} \text{ or } \mathbb{F}_{\text{fp32}}^{4 \times 4}, \text{ and } \mathbf{A}, \mathbf{B} \in \mathbb{F}_{\text{fp16}}^{4 \times 4},$$

and employs *full* precision products and fp32 summation accumulate. Here, the *full* precision multiplication is exact as explained in section 2. In [6], the authors investigate all four possible matrix-matrix multiplication routines in TensorCore, which depend on whether \mathbf{C} and \mathbf{D} are computed in fp16 or fp32. They also note that matrices larger than 4-by-4 can still be computed using this block FMA by accumulating matrix sums with $\mathbf{C} \in \mathbb{F}_{\text{fp32}}^{4 \times 4}$. Suppose that we aim to compute

619 a fp16 matrix product of two fp16 matrices, $\mathbf{X} \in \mathbb{F}_{(fp16)}^{m \times p}$, $\mathbf{Y} \in \mathbb{F}_{(fp16)}^{p \times n}$, and $\mathbf{Z} = \mathbf{XY} \in \mathbb{F}_{fp16}^{m \times n}$. We
 620 pad \mathbf{X}, \mathbf{Y} with zeros so that all matrix dimensions are multiples of 4 and the matrix product can
 621 be computed with the TensorCore block FMA. Let $\mathbf{Q}_{[i,j]} := \mathbf{Q}[4(i-1)+1:4i, 4(j-1)+1:4j]$
 622 refer to the $(i, j)^{th}$ 4-by-4 block for any $\mathbf{Q} \in \{\mathbf{X}, \mathbf{Y}, \mathbf{Z}\}$. Then, we compute $\mathbf{Z}_{[i,j]}$ via

$$623 \quad \mathbf{Z}_{[i,j]} = \sum_{k=1}^{\lceil p/4 \rceil} \mathbf{X}_{[i,k]} \mathbf{Y}_{[k,j]},$$

624 where we use (4.4) by initializing with $\mathbf{A}^{(1)} := \mathbf{X}_{[i,1]}$, $\mathbf{B}^{(1)} := \mathbf{Y}_{[1,j]}$, and $\mathbf{C}^{(1)} := \mathbf{0}_{4 \times 4}$ and setting
 625 $\mathbf{A}^{(k)} := \mathbf{X}_{[i,k]}$, $\mathbf{B}^{(k)} := \mathbf{Y}_{[k,j]}$, and $\mathbf{C}^{(k)} := \mathbf{D}^{(k-1)}$ for $k = 2 : \lceil p/4 \rceil$. By setting $\mathbf{C}^{(k)}, \mathbf{D}^{(k)} \in \mathbb{F}_{fp32}^{4 \times 4}$
 626 for $k > 1$ and only casting down at the end via $\mathbf{Z}_{[i,j]} = \text{fp16}(\mathbf{D}^{(\lceil p/4 \rceil)})$, we mostly employ fp32
 627 arithmetic for a mixed precision matrix product routine whose inputs and output are in fp16. For
 628 example, take $p = 8$. Then,

$$629 \quad \mathbf{D}^{(1)} = \text{fl}_{TC}(\mathbf{X}_{[i,1]} \mathbf{Y}_{[1,j]}), \quad \mathbf{D}^{(2)} = \text{fl}_{TC}(\mathbf{X}_{[i,2]} \mathbf{Y}_{[2,j]} + \mathbf{D}^{(1)}) \in \mathbb{F}_{fp32}^{4 \times 4}$$

$$630 \quad \mathbf{Z}_{[i,j]} = \text{castdown}(\mathbf{D}^{(2)}) \in \mathbb{F}_{fp16}^{4 \times 4}.$$

632 Adapting the rounding error analysis in [6] into this specific mixed precision matrix product setting
 633 yields the componentwise forward bound

$$634 \quad (4.5) \quad |\mathbf{Z} - \text{fl}(\mathbf{Z})| \leq \left(u^{(fp16)} + \gamma_{p/4}^{(fp32)} + u^{(fp16)} \gamma_{p/4}^{(fp32)} \right) |\mathbf{X}| |\mathbf{Y}|.$$

635 **4.1.1. Round down at block level: BQR.** Consider the input matrix, $\mathbf{A} \in \mathbb{F}_l^{m \times n}$, parti-
 636 tioned into N blocks of r columns, $\mathbf{A} = [\mathbf{C}_1 \cdots \mathbf{C}_N]$ as in subsection 3.2. Algorithm 7 shows a mixed
 637 precision variant of BQR that maximizes the use of bFMAs but uses high precision arithmetic for
 638 level-1 and 2 BLAS operations which are only a $\mathcal{O}(1/N)$ fraction of the total number of FLOPs.
 639 Each block is casted up to compute a high precision HQR and to form the WY representation.
 640 The WY representation is then casted down to low precision since the bFMAs require low precision
 641 inputs for matrix products, and the \mathbf{R} factor from the high precision HQR can be casted down to
 642 return a low precision \mathbf{R} factor at the very end. Since the cast down operations for the \mathbf{R} factor
 643 and the WY representations occur at every block, we can expect columnwise error bound for alg. 7
 644 to increase by approximately $Nu^{(l)}$ from the error bound for alg. 5.

645 *Rounding Error Analysis.* Since $\hat{\mathbf{W}}_k, \hat{\mathbf{Y}}_k$'s are computed with alg. 4 in high precision then cast
 646 down, the new low precision WY update is $\hat{\mathbf{X}}_k^{(l)} = \mathbf{I} - \mathbf{I}^{(l)} \hat{\mathbf{W}}_k \mathbf{I}^{(l)} \hat{\mathbf{Y}}_k^{(\top)}$. Consider applying $\hat{\mathbf{X}}_k^{(l)}$ to
 647 some matrix stored in low precision, \mathbf{B} using the TensorCore bFMAs. We analyze a single column
 648 $\mathbf{b}_j := \mathbf{B}[:, j] \in \mathbb{F}_l^{m-(k-1)r}$ even though this operation is done on \mathbf{B} as a whole. Let

$$649 \quad \mathbf{I}^{(l)} \hat{\mathbf{W}}_k = (\mathbf{I} + \mathbf{E}_W) \hat{\mathbf{W}}_k, \quad \mathbf{I}^{(l)} \hat{\mathbf{Y}}_k = (\mathbf{I} + \mathbf{E}_Y) \hat{\mathbf{Y}}_k,$$

650 where $\mathbf{E}_W, \mathbf{E}_Y$ are diagonal and bounded componentwise by $u^{(l)}$. The rounding errors for forming
 651 $\hat{\mathbf{W}}_k$ and $\hat{\mathbf{Y}}_k$ remain the same since these are computed in high precision. Therefore, we first include
 652 errors introduced from casting down the WY representation and compute the matrix norm error of

Algorithm 7: $\hat{\mathbf{Q}}_{mpBQR3}, \hat{\mathbf{R}}_{mpBQR3} \leftarrow \text{mpBQR3}(\mathbf{A}, r)$: Perform a mixed precision variant of BQR of \mathbf{A} with column partitions of size r . $\hat{\mathbf{Q}}_{mpBQR3}, \hat{\mathbf{R}}_{mpBQR3}$, and $\hat{\mathbf{A}}$ are represented in low precision. Matrix-matrix multiplication and accumulate operations in lines 10, 13, and 14 require low precision inputs but can return in either of the two precisions.

<p>Input: \mathbf{A}, r.</p> <pre> 1 $N = \frac{n}{r}$ 2 for $k = 1 : N - 1$ do 3 $\mathbf{V}_k, \beta_k, \mathbf{C}_k \leftarrow \text{hhQR}(\text{castup}(\mathbf{C}_k))$ 4 $\mathbf{C}_k \leftarrow \text{castdown}(\mathbf{C}_k)$ 5 $\mathbf{W}_k \leftarrow \text{buildWY}(\mathbf{V}_k, \beta_k)$ 6 $[\mathbf{V}_k, \mathbf{W}_k] \leftarrow \text{castdown}([\mathbf{V}_k, \mathbf{W}_k])$ 7 $[\mathbf{C}_{k+1} \cdots \mathbf{C}_N] \leftarrow \mathbf{V}_k (\mathbf{W}_k^\top [\mathbf{C}_{k+1} \cdots \mathbf{C}_N])$ 8 $\mathbf{Q} \leftarrow \mathbf{I}$ 9 for $k = N : -1 : 1$ do 10 $\mathbf{Q}[(k-1)r+1 : m, (k-1)r+1 : n] \leftarrow \mathbf{W}_k (\mathbf{V}_k^\top \mathbf{Q}[(k-1)r+1 : m, (k-1)r+1 : n])$ 11 return \mathbf{Q}, \mathbf{A}</pre>	<p>Output: $\hat{\mathbf{Q}}_{mpBQR3}, \hat{\mathbf{R}}_{mpBQR3}$ /* Let $\mathbf{A} = [\mathbf{C}_1 \cdots \mathbf{C}_N]$. */</p> <p>/* Algorithm 3 in high precision. */ /* Builds \mathbf{R} factor in low precision. */ /* Algorithm 4 in high precision */ /* returned in low precision */ /* Build \mathbf{Q}: \mathbf{I}_m if full QR, and $\mathbf{I}_{m \times n}$ if thin QR. */</p>
-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

653 forming $\hat{\mathbf{X}}_k^{(l)}$,

$$\begin{aligned}
654 \quad \|\hat{\mathbf{X}}_k^{(l)} - \mathbf{X}_k\|_F &= \|-(\mathbf{I} + \mathbf{E}_W + \mathbf{E}_Y + \mathbf{E}_W \mathbf{E}_Y) \hat{\mathbf{W}}_k \hat{\mathbf{Y}}_k^\top + \mathbf{W}_k \mathbf{Y}_k^\top\|_F, \\
655 \quad &\leq \left((1 + \gamma_2^{(l)} + (u^{(l)})^2) r \tilde{\gamma}_{m-(k-1)r}^{(h)} + \gamma_2^{(l)} + (u^{(l)})^2 \right) \|\mathbf{X}_k\|_F \\
656 \quad &\leq \tilde{\gamma}_2^{(l)} + r \tilde{\gamma}_{m-(k-1)r}^{(h)} + r \gamma_2^{(l)} \tilde{\gamma}_{m-(k-1)r}^{(h)}.
\end{aligned}$$

658 Now, we consider the backward error of applying $\hat{\mathbf{X}}_k^{(l)}$ to \mathbf{b}_j with the bFMA matrix product error
659 bound from (4.5). The multiplication by $(\mathbf{I}^{(l)} \hat{\mathbf{Y}}_k)^\top$ yields backward error bounded by

$$660 \quad \text{fl}_{TC}((\mathbf{I}^{(l)} \hat{\mathbf{Y}}_k)^\top \mathbf{b}_j) = (\hat{\mathbf{Y}}_k + \Delta_{TC} \hat{\mathbf{Y}}_k) \mathbf{b}_j, \quad |\Delta_{TC} \hat{\mathbf{Y}}_k| \leq u^{(l)} + \gamma_{\frac{m-(k-1)}{4}}^{(h)} + u^{(l)} \gamma_{\frac{m-(k-1)}{4}}^{(h)} |\hat{\mathbf{Y}}_k| |\mathbf{b}_j|,$$

661 and the subsequent multiplication by $(\mathbf{I}^{(l)} \hat{\mathbf{W}}_k)$ and subtraction from \mathbf{b}_j result in,

$$\begin{aligned}
662 \quad \text{fl}_{TC}(\hat{\mathbf{X}}_k^{(l)} \mathbf{b}_j) &= (\hat{\mathbf{X}}_k^{(l)} + \Delta^{(l)} \mathbf{X}_k) \mathbf{b}_j, \\
663 \quad |\Delta^{(l)} \mathbf{X}_k| &\leq \left(\gamma_2^{(l)} + \gamma_{1+\frac{m-(k-2)}{4}}^{(h)} + \gamma_2^{(l)} \gamma_{1+\frac{m-(k-2)}{4}}^{(h)} \right) (|\mathbf{b}_j| + |\mathbf{I}^{(l)} \hat{\mathbf{W}}_k| |\mathbf{I}^{(l)} \hat{\mathbf{Y}}_k|^\top |\mathbf{b}_j|). \\
664
\end{aligned}$$

665 Converting to a normwise error bound using the same logic from (3.9) and (3.10), we result in

$$666 \quad (4.6) \quad \|\text{fl}_{TC}(\hat{\mathbf{X}}_k^{(l)} \mathbf{b}_j) - \mathbf{X}_k \mathbf{b}_j\|_2 \leq (\tilde{\gamma}_2^{(l)} + r \tilde{\gamma}_{m-(k-1)r}^{(h)} + r \gamma_2^{(l)} \tilde{\gamma}_{m-(k-1)r}^{(h)}) \|\mathbf{b}_j\|_2,$$

667 since the rounding errors from the bFMAs are small in comparison to the errors from casting down
668 the WY representation built in high precision. The corresponding matrix error bound is

$$669 \quad (4.7) \quad \|\text{fl}_{TC}(\hat{\mathbf{X}}_k^{(l)}) - \mathbf{X}_k\|_F \leq \tilde{\gamma}_2^{(l)} + r \tilde{\gamma}_{m-(k-1)r}^{(h)} + r \gamma_2^{(l)} \tilde{\gamma}_{m-(k-1)r}^{(h)}.$$

670 We can finally compute the forward errors from implementing [alg. 7](#). Consider the j^{th} column
 671 of the \mathbf{Q} factor, which we denote with $\mathbf{q}_j := \hat{\mathbf{Q}}_{mpBQR3}[:, j]$, and let $k = \lfloor j/r \rfloor$. for $k' = 1 : N$, and
 672 (4.7) was used to invoke [Lemma 3.2](#). Then the columnwise error is

$$673 \quad (4.8) \quad \|\Delta \mathbf{q}_j\|_2 \leq -1 + \prod_{k'=1}^k (1 + \tilde{\gamma}_2^{(l)})(1 + r\tilde{\gamma}_{m-(k'-1)r}^{(h)})$$

$$674 \quad (4.9) \quad \leq k\tilde{\gamma}_2^{(l)} + kr\tilde{\gamma}_m^{(h)} + k^2r\tilde{\gamma}_2^{(l)}\tilde{\gamma}_m^{(h)},$$

676 where $\Delta \mathbf{q}_j = (\text{fl}_{TC}(\hat{\mathbf{X}}_1^{(l)}) \cdots \text{fl}_{TC}(\hat{\mathbf{X}}_k^{(l)}) - \mathbf{X}_1 \cdots \mathbf{X}_k)\hat{\mathbf{e}}_j$. Summing over the columns to find a matrix
 677 norm error bound yields

$$678 \quad (4.10) \quad \|\hat{\mathbf{Q}}_{mpBQR} - \mathbf{Q}\|_F \leq n^{1/2}\tilde{\gamma}_N^{(l)} + n^{(3/2)}\tilde{\gamma}_m^{(h)},$$

679 where the summation of the third term in (4.9) is swept under the tilde notation in $n^{1/2}\tilde{\gamma}_N^{(l)}$.
 680 This bound shows that [alg. 7](#) only adds $n^{1/2}\tilde{\gamma}_N^{(l)}$ order errors to the bounds in (3.24). Using that
 681 $u^{(l)} = M_{l,h}u^{(h)}$, this increase corresponds to a multiplicative factor shown below,

$$682 \quad (4.11) \quad n^{1/2}\tilde{\gamma}_N^{(l)} + n^{(3/2)}\tilde{\gamma}_m^{(h)} \approx \left(1 + \frac{M_{l,h}}{rm}\right) n^{(3/2)}\tilde{\gamma}_m^{(h)}.$$

683 Therefore, the loss in accuracy due to mixed precision computing is relatively small when the
 684 disparity in precision ($M_{l,h}$) is small in comparison to the block size, mr . Whether this loss in
 685 accuracy in the worst-case scenario is worth the speed-ups from using mixed precision hardware
 686 is an open question that can be tackled in future research. We expect that the block size r , the
 687 dimension of the input matrix m, n , and hardware specificities will be contributing factors.

688 **4.1.2. Round down at block level: TSQR.** Let us now consider a variant of TSQR, where
 689 all instances of `hh_mult` are replaced by some level-3 BLAS operations. Note that for all blocks
 690 in all levels, exactly n HH transformations of lengths either $m2^{-L}$ or $2n$ are applied via `hh_mult`.
 691 Let $\tilde{m} := \max\{m2^{-L}, 2n\}$ be the larger of the two. We consider two ways of applying n HH
 692 transformations with level-3 BLAS operations.

- 693 1. Consider building the WY representation using high precision arithmetic, casting them
 694 down and then applying the update with TensorCore block FMAs. The multiplication by
 695 the \mathbf{Y} factor requires at most \tilde{m} -length inner products and a cast down operation and the
 696 multiplication by the \mathbf{W} factor requires n -length inner products and another cast down
 697 operation. The errors accumulated from these actions are bounded by $\mathcal{O}(3u^{(l)} + \tilde{\gamma}_{\tilde{m}n}^{(h)})$
 698 componentwise.
- 699 2. Now, consider applying the n HH transformations by forming the operator explicitly then
 700 computing a single matrix-matrix product. We form the operator using the same steps as
 701 forming the \mathbf{Q} factor in HQR in high precision arithmetic, then cast the result down. The
 702 construction of the operator and the cast down result in error bounded by $\mathcal{O}(u^{(l)} + \tilde{\gamma}_{\tilde{m}n}^{(h)})$,
 703 and the matrix-matrix product requires \tilde{m} -length inner products and another cast down
 704 operation. This option also accrues error bounded by $\mathcal{O}(2u^{(l)} + \tilde{\gamma}_{\tilde{m}n}^{(h)})$.

705 Both of these options require more FLOPs than in the standard algorithm implemented with
 706 level-2 BLAS operations, since the same number of level-2 BLAS operations are required to form
 707 the matrices required for the level-3 variants. The level-3 variants are built during the formation

of the \mathbf{R} factor and can be reused when forming the \mathbf{Q} factor. Notice that unlike BQR which is rich in level-3 BLAS operations by design, it is not clear whether implementing TSQR with level-3 BLAS operations has obvious benefits. Regardless, we still perform a rounding error analysis of TSQR performed with mixed precision level-3 BLAS operations, i.e. TensorCore block FMAs.

The analysis in [20] shows that each column of \mathbf{Q} is transformed by n HH transformations of length $2n$ from levels $L : -1 : 1$, and another set of n HH transformations of length $m2^{-L}$ at level 0. We can easily modify the analysis in [20] and applying Lemma 3.2 by adding $(1 + 2u^{(l)})$ to every set of n HH transformations in each level. There are two low precision rounding errors in each block per level since casting down the matrix operator formed with high precision is cast down to the low precision, and the matrix-matrix product used in applying this operator with TensorCore block FMAs incurs another low precision rounding error. Therefore, all instances of $n\tilde{\gamma}_{m2^{-L}}, n\tilde{\gamma}_{2n}$ are replaced with

$$(1 + 2u^{(l)})(1 + n\tilde{\gamma}_{m2^{-L}}^{(h)}) - 1, \quad \text{and} \quad (1 + 2u^{(l)})(1 + n\tilde{\gamma}_{2n}^{(h)}) - 1.$$

Then, the \mathbf{Q} factor formed with this mixed precision variant of TSQR is denoted with $\hat{\mathbf{Q}}_{mpTSQR}$ and its j^{th} column has rounding errors bounded by,

$$(4.12) \quad \|\hat{\mathbf{Q}}_{mpTSQR}[:, j] - \mathbf{Q}[:, j]\|_2 \leq \tilde{\gamma}_{L+1}^{(l)} + n \left(L\tilde{\gamma}_{2n}^{(h)} + \tilde{\gamma}_{m2^{-L}}^{(h)} \right).$$

Summing up the columns for a matrix norm error bound, we result in

$$(4.13) \quad \|\hat{\mathbf{Q}}_{mpTSQR} - \mathbf{Q}\|_F \leq n^{1/2}\tilde{\gamma}_{L+1}^{(l)} + n^{3/2} \left(L\tilde{\gamma}_{2n}^{(h)} + \tilde{\gamma}_{m2^{-L}}^{(h)} \right).$$

Therefore, we can convert the additional low precision rounding errors into a multiplicative factor of the original bound in (3.26),

$$(4.14) \quad n^{1/2}\tilde{\gamma}_{L+1}^{(l)} + n^{3/2} \left(L\tilde{\gamma}_{2n}^{(h)} + \tilde{\gamma}_{m2^{-L}}^{(h)} \right) = \left(1 + \frac{M_{l,h}L}{n(2nL + m2^{-L})} \right) n^{3/2} \left(L\tilde{\gamma}_{2n}^{(h)} + \tilde{\gamma}_{m2^{-L}}^{(h)} \right).$$

Once again, the constant that represents the disparity in the two precisions, $M_{l,h}$ is compared against the original matrix size m, n and the block size specifications defined by 2^L and the number of levels, L .

4.2. Round down at inner-product. While the previous section discussed blocked variants of HQR that can be easily adapted for the mixed precision setting specific to TensorCore’s level-3 BLAS operations, we want to provide a more general mixed precision environment in this section. Recall that HQR, BQR, and TSQR all rely on HH transformations in one way or another, and HH transformations are essentially performed via (3.8). This implementation capitalizes on the rank-1 update structure of HH transformations where the predominant share of FLOPs is spent on an inner product, and computing the HH vector and constant also rely heavily on inner products. Therefore, we can attribute nearly all of the computational tasks for algs. 3, 5 and 6 to the inner product. In addition, the inner product is just as important in non-HQR linear algebra tools, where some examples include projections and matrix-vector, matrix-matrix multiply. Consequently, we return to the mixed precision setting described in section 2, where every inner product is cast down to the lower precision as shown in (2.10).

4.2.1. Round down at inner product: HQR. Consider forming a HH transformation that zeros out $\mathbf{x} \in \mathbb{R}^m$ below the i^{th} element. We need to compute σ , β , $\tilde{\mathbf{v}}_1$, and \mathbf{v} as defined in subsection 3.1:

$$(4.15) \quad \text{fl}(\sigma) = \text{fl}(-\text{sign}(\mathbf{x}[1])\|\mathbf{x}\|_2) = \sigma + \Delta\sigma, \quad |\Delta\sigma| \leq (\gamma_2^{(l)} + \gamma_m^{(h)} + \gamma_2^{(l)}\gamma_m^{(h)})|\sigma|,$$

$$(4.16) \quad \text{fl}(\tilde{\mathbf{v}}[1]) = \tilde{\mathbf{v}}[1] + \Delta\tilde{\mathbf{v}}[1] = (1 + \delta^{(l)})(\mathbf{x}[1] - \sigma - \Delta\sigma), \quad |\Delta\tilde{\mathbf{v}}[1]| \leq (\gamma_3^{(l)} + \tilde{\gamma}_m^{(h)})|\tilde{\mathbf{v}}[1]|$$

$$(4.17) \quad \text{fl}(\beta) = \beta + \Delta\beta = (1 + \delta^{(l)})(-\tilde{\mathbf{v}}[1]/\hat{\sigma}), \quad |\Delta\beta| \leq (\gamma_8^{(l)} + \tilde{\gamma}_m^{(h)})|\beta|,$$

$$(4.18) \quad \text{fl}(\mathbf{v}[j]) = \mathbf{v}[j] + \Delta\mathbf{v}[j] \text{ where } |\Delta\mathbf{v}_j| \leq \begin{cases} 0, & j = 1 \\ (\gamma_7^{(l)} + \tilde{\gamma}_m^{(h)})|\mathbf{v}_j|, & j = 2 : m - i + 1. \end{cases}$$

These bounds on $\Delta\sigma$, $\Delta\tilde{\mathbf{v}}[1]$, $\Delta\beta$, and $\Delta\mathbf{v}[j]$ are computed by using the rules from Lemma 2.4 on the analysis shown in subsection 3.1. Using these, we can formulate the mixed precision version of (3.9) where $\hat{\mathbf{y}} = \text{fl}(\mathbf{P}_\mathbf{v}\mathbf{x}) \in \mathbb{R}^m$ is implemented via (3.8). Note that the inner product $\hat{\mathbf{v}}^\top \mathbf{x}$ is computed with the mixed precision inner product scheme outlined in Assumption 2.3, and all other operations are done in the lower precision. Then, the transformed vector is bounded by

$$(4.19) \quad \hat{\mathbf{y}} = \mathbf{y} + \Delta\mathbf{y}, \quad \|\Delta\mathbf{y}\|_2 \leq (\gamma_{25}^{(l)} + \tilde{\gamma}_m^{(h)})\|\mathbf{y}\|_2.$$

Thus, a backward error can be formed using $\Delta\mathbf{P}_\mathbf{v} = \Delta\mathbf{y}\mathbf{x}^\top / \|\mathbf{x}\|_2^2$,

$$(4.20) \quad \hat{\mathbf{y}} = (\mathbf{P}_\mathbf{v} + \Delta\mathbf{P}_\mathbf{v})\mathbf{x}, \quad \|\Delta\mathbf{P}_\mathbf{v}\|_F \leq (\gamma_{25}^{(l)} + \tilde{\gamma}_m^{(h)}).$$

Now, we form the error bounds for applying n HH transformations to \mathbf{x} using Lemma 3.2,

$$(4.21) \quad \hat{\mathbf{y}} = \mathbf{Q}(\mathbf{x} + \Delta\mathbf{x}) = (\mathbf{Q} + \Delta\mathbf{Q})\mathbf{x},$$

$$(4.22) \quad \|\Delta\mathbf{y}\|_2 \leq (\tilde{\gamma}_n^{(l)} + n\tilde{\gamma}_m^{(h)})\|\mathbf{x}\|_2, \quad \|\Delta\mathbf{Q}\|_F \leq (\tilde{\gamma}_n^{(l)} + n\tilde{\gamma}_m^{(h)}).$$

Note that we have additionally assumed that $25 \ll n$ and used the $\tilde{\gamma}^{(l)}$ notation. The analogous mixed precision QR factorization error bounds are shown in Theorem 4.1.

THEOREM 4.1. *Let $\mathbf{A} \in \mathbb{R}^{m \times n}$ with $m \geq n$ have full rank, n . Let $\hat{\mathbf{Q}}_{mpHQR} \in \mathbb{R}^{m \times n}$ and $\hat{\mathbf{R}} \in \mathbb{R}_{mpHQR}^{n \times n}$ be the thin QR factors of \mathbf{A} obtained via alg. 3 with mixed precision FLOPs where inner products are computed in precision h then cast down. All other operations are carried out in precision l . Then,*

$$\|\Delta\mathbf{R}_{mpHQR}[:, j]\|_2 \leq (\tilde{\gamma}_n^{(l)} + n\tilde{\gamma}_m^{(h)})\|\mathbf{A}[:, j]\|_2, \quad \|\Delta\mathbf{R}_{mpHQR}\|_F \leq (\tilde{\gamma}_n^{(l)} + n\tilde{\gamma}_m^{(h)})\|\mathbf{A}\|_F$$

$$\|\Delta\mathbf{Q}[:, j]_{mpHQR}\|_2 \leq (\tilde{\gamma}_n^{(l)} + n\tilde{\gamma}_m^{(h)}), \quad \|\Delta\mathbf{Q}_{mpHQR}\|_F \leq n^{1/2}(\tilde{\gamma}_n^{(l)} + n\tilde{\gamma}_m^{(h)}).$$

4.2.2. Round down at inner product: BQR. Now, we analyze alg. 5 with the mixed precision inner product scheme of Assumption 2.3. At the k^{th} block, we first apply the mixed precision HQR summarized in Theorem 4.1. Next, we construct the WY representation, where we can now use (4.19) and (4.20) and Lemma 3.2 to form

$$(4.23) \quad \|\hat{\mathbf{X}}_k^{(l)} - \mathbf{X}_k\|_F = \|(\hat{\mathbf{P}}_k^{(1)} \cdots \hat{\mathbf{P}}_k^{(r)}) - (\mathbf{P}_k^{(1)} \cdots \mathbf{P}_k^{(r)})\|_F \leq \tilde{\gamma}_r^{(l)} + r\tilde{\gamma}_m^{(h)}.$$

Then, the j^{th} column of the \mathbf{Q} factor resulting from this mixed precision variant of BQR incurs rounding errors bounded by

$$(4.24) \quad \|\hat{\mathbf{Q}}_{mpBQR2}[:, j]\|_F = \|\hat{\mathbf{X}}_1 \cdots \hat{\mathbf{X}}_N \hat{\mathbf{e}}_j\|_2 \leq N\tilde{\gamma}_r^{(l)} + n\tilde{\gamma}_m^{(h)},$$

and the matrix norm error bound is,

$$(4.25) \quad \|\hat{\mathbf{Q}}_{mpBQR2}\|_F \leq n^{1/2}N\tilde{\gamma}_r^{(l)} + n^{3/2}\tilde{\gamma}_m^{(h)} \approx \left(1 + \frac{M_{l,h}}{m}\right) n^{3/2}\tilde{\gamma}_m^{(h)}.$$

Recall that the block mixed precision variant of [section 4.1.1](#) yielded a multiplicative factor of $(1 + \frac{M_{l,h}}{rm})$ (see [\(4.11\)](#)). This implies that the mixed precision inner product introduces low precision error $r \times$ larger than the low precision errors incurred from casting down at the block level. However, if m is sufficiently larger than $M_{l,h}$, the mixed precision inner product can still had non-leading order error terms to the worst-case scenario.

4.2.3. Round down at inner product: TSQR. Finally, we consider using the mixed precision inner product of [Assumption 2.3](#) in [alg. 6](#). This corresponds to replacing every instance of $n\tilde{\gamma}_{m'}$ for $m' \in \{2n, m2^{-L}\}$ in [Theorem 3.7](#) with $\tilde{\gamma}_n^{(l)} + n\tilde{\gamma}_{m'}^{(h)}$. We first consider the norm errors for the j^{th} column of the \mathbf{Q} factor computed by this mixed precision variant of [alg. 6](#),

$$(4.26) \quad \|\hat{\mathbf{Q}}_{mpTSQR2}[:, j] - \mathbf{Q}[:, j]\|_2 \leq (L+1)\tilde{\gamma}_n^{(l)} + n(\tilde{\gamma}_{m2^{-L}}^{(h)} + L\tilde{\gamma}_{2n}^{(h)}).$$

Then, the matrix norm error bound is

$$(4.27) \quad \|\hat{\mathbf{Q}}_{mpTSQR2} - \mathbf{Q}\|_F \leq n^{1/2}(L+1)\tilde{\gamma}_n^{(l)} + n^{3/2}(\tilde{\gamma}_{m2^{-L}}^{(h)} + L\tilde{\gamma}_{2n}^{(h)})$$

$$(4.28) \quad \approx \left(1 + \frac{M_{l,h}L}{m2^{-L} + 2Ln}\right) n^{3/2}(\tilde{\gamma}_{m2^{-L}}^{(h)} + L\tilde{\gamma}_{2n}^{(h)}).$$

5. Numerical Experiments.

6. Conclusion. Though the use of lower precision naturally reduces the bandwidth and storage needs, the development of GPUs to optimize low precision floating point arithmetic have accelerated the interest in half precision and mixed precision algorithms. Loss in precision, stability, and representable range offset for those advantages, but these shortcomings may have little to no impact in some applications. It may even be possible to navigate around those drawbacks with algorithmic design.

The existing rounding error analysis cannot accurately bound the behavior of mixed precision arithmetic. We have developed a new framework for mixed precision rounding error analysis and applied it to HQR, a widely used linear algebra routine, and implemented it in an iterative eigensolver in the context of spectral clustering. The mixed precision error analysis builds from the inner product routine, which can be applied to many other linear algebra tools as well. The new error bounds more accurately describe how rounding errors are accumulated in mixed precision settings. We also found that TSQR, a communication-avoiding, easily parallelizable QR factorization algorithm for tall-and-skinny matrices, can outperform HQR in mixed precision settings for ill-conditioned, extremely overdetermined cases, which suggests that some algorithms are more robust against lower precision arithmetic.

Although this work is focused on QR factorizations and applications in spectral clustering, the mixed precision round-off error analysis can be applied to other tasks and applications that

can benefit from employing low precision computations. While the emergence of technology that support low precision floats combats issues dealing with storage, now we need to consider how low precision affects stability of numerical algorithms.

Future work is needed to test larger, more ill-conditioned problems with different mixed precision settings, and to explore other divide-and-conquer methods like TSQR that can harness parallel capabilities of GPUs while withstanding lower precisions.
